Chapter 1

Inside the archiso

This section is aimed at providing help with the general installation of a customized Arch Linux from within an official Arch Linux image (archiso).

NOTE: As Arch Linux is a rolling release Linux distribution, it is advised, to have a working internet connection, in order to get the latest package upgrades and to install additional software, as the archiso only has very few packages available from cache.

Furthermore, one should bear in mind that depending on the version, or rather modification date, the guide may already be outdated. If you encounter any problems along the way, you will either have to resolve the issue yourself, or utilize the great ArchWiki, or the Arch Linux forums.

1.1 Syncing up pacman

First of all we need to sync up pacman's package repository, in order to be able to install packages

```
root@archiso ~ # pacman -Sy
```

WARNING: Using pacman -Sy should be sufficient, in order to be able to search for packages from within the archiso, without upgrading the system, but might break your system, if you use this command on an existing installation!

To be on the safe side, it is advised to always use pacman -Syu instead! pacstrap uses the latest packages anyways.

1.1.1 Official repositories

After doing that, we can now install any software from the official repositories by issuing

```
root@archiso ~ # pacman -S <package_name>
```

where you would replace <package_name> with the actual package name.

If you don't know the exact package name, or if you just want to search for a keyword, for example xfce to list all packages having to do something with xfce, use

```
root@archiso ~ # pacman -Ss <keyword>
```

If you want to remove an installed package, just use

```
root@archiso ~ # pacman -Rsu <package_name>
```

CAUTION: If you have to force remove, which you should use **with extreme caution**, you can use

```
root@archiso ~ # pacman -Rdd <package_name>
```

1.1.2 AUR.

If you want to install a package from the AUR, I would proceed as follows

cd into the dedicated directory, if you're using the dotfiles repo, which
provides an update.sh script within that folder, to check every subfolder
for updates

```
dustvoice@archiso ~ $ cd AUR
```

2. Clone the package with git

```
dustvoice@archiso ~/AUR $ git clone

   https://aur.archlinux.org/pacman-git.git
```

3. Switch to the package directory

```
dustvoice@archiso ~/AUR $ cd pacman-git
```

4. Execute makepkg

```
dustvoice@archiso ~/AUR/pacman-git $ makepkg -si
```

5. Delete all files created by makepkg, in order to easily see, if a package needs an update by using git fetch --all and git status

```
dustvoice@archiso ~/AUR/pacman-git $ git reset HEAD

→ --hard
dustvoice@archiso ~/AUR/pacman-git $ git clean -fdx
```

NOTE: You might have to resolve any AUR dependencies, which can't be resolved with pacman.

WARNING: In order to install that AUR package, you **must** switch to your normal user, because **makepkg** doesn't run as root.

NOTE: There is an update.sh bash script available in the AUR directory, when using the dotfiles repository, which enables you to quickly check all installed AUR packages for updates and even install them in the same step.

Issue ./update.sh --help for command line options.

1.1.3 Software categories

There are three categories of software in this guide:

- Console software is intended to be used with either the native linux console, or with a terminal emulator
- GUI software is intended to be used in a graphical desktop environment
- Hybrid software can either be used within both a console and a graphical desktop environment (networkmanager), or there are packages available for both console and a graphical desktop environment (pulseaudio with pulsemixer for console and pavucontrol for GUI

1.1.4 Software installation

In this guide, I'll be explicitly mark the packages installed in a specific section.

This enables you to

- clearly see what packages get installed / need to be installed in a specific section
- install packages before you start with the section in order to minimize waiting time
- not have to read through bloating lines like

```
dustvoice@DustArch ~
$ sudo pacman -S some-package
```

• not have to accidentally reinstall already installed packages

NOTE: The packages are always the recommended packages.

For further clarification for specific packages (e.g. UEFI specific packages), continue reading the section, as there is most certainly a explanation there.

Of course, you can adapt everything to your needs, especially in the step.

Example section

core	libutil-linux		
extra	git		
community	ardour cadence jsampler linuxsampler qsampler sample-package		
AUR	sbupdate		

You have to configure sample-package by editing /etc/sample.conf

Sample.text=useful	
--------------------	--

1.2 Formatting the drive

First you have to list all the available drives by issuing

```
root@archiso ~ # fdisk -l
```

 $\bf NOTE:$ The output of ${\tt fdisk}$ -1 is dependent on your system configuration.

1.2.1 The standard way

In my case, the partition I want to install the root file system on is /dev/sdb2. /dev/sdb3 will be my swap partition.

NOTE: A swap size twice the size of your RAM is recommended by a lot of people.

With bigger RAM sizes available today, this isn't necessary anymore. To be exact, every distribution has different recommendations for swap sizes.

Also swap size heavily depends on whether you want to be able to hibernate, etc.

You should make the swap size at least your RAM size and for RAM sizes over 4GB and the wish to hibernate, at least one and a half your RAM size.

IMPORTANT: If you haven't yet partitioned your disk, please refer to the general partitioning tutorial in the ArchWiki.

Now we need to format the partitions accordingly

```
root@archiso ~ # mkfs.ext4 /dev/sdb2
root@archiso ~ # mkswap /dev/sdb3
```

After doing that, we can turn on the swap and mount the root partition.

```
root@archiso ~ # swapon /dev/sdb3
root@archiso ~ # mount /dev/sdb2 /mnt
```

NOTE: If you have an additional EFI system partition, because of a *UEFI* - *GPT* setup or e.g. an existing Windows installation, which we will assume to be located under /dev/sda2 (/dev/sda is the disk of my Windows install), you'll have to mount this partition to the new systems /boot folder

```
root@archiso ~ # mkdir /mnt/boot
root@archiso ~ # mount /dev/sda2 /mnt/boot
```

1.2.2 Full system encryption

NOTE: This is only one way to do it and it is the way I have done it. I'm using a LVM on LUKS setup, with lvm2 and luks2. For more information look into the ArchWiki.

NOTE: This setup has different partitions used for the EFI System Partition, the root partition, etc. than used in the rest of the guide. If you want to use grub in conjunction with some full system encryption, you would have to adapt the disk and partition names accordingly. The only part of the guide, which currently uses the drive/partition naming scheme used in this section is The manual way.

So first we have to decide, which disk, or partition is going to hold the luks2 encrypted lvm2 stuff.

In my case I'm now using my NVMe SSD, with a GPT partition scheme, for both the EFI System Partition, in my case /dev/nvmeOn1p1, defined as a EFI System partition type in fdisk, as well as the main LUKS volume, in my case /dev/nvmeOn1p2, defined as a Linux filesystem partition type in fdisk.

After partitioning our disk, we now have to set everything up.

EFI System Partition

core	dosfstools

I won't setup my ${\tt EFI}$ System Partition with cryptsetup, as it makes no sense in my case.

Every EFI binary (or STUB) has to be signed with my own Secure Boot keys, as described in The manual way, so tempering with the EFI System Partition poses no risk to my system.

Instead I will simply format it with a FAT32 file system

```
root@archiso ~ # mkfs.fat -F 32 -L /efi /dev/nvmeOn1p1
```

We will bother with mounting it later on.

First off we have to create the LUKS volume

After that we have to open the volume

```
root@archiso ~ # cryptsetup open /dev/nvmeOn1p2 cryptroot
```

The volume is now accessible under /dev/mapper/cryptroot.

core lvm2

I'm going to create one PV (Physical Volume) with the just created and opened cryptroot LUKS volume, one VG (Volume Group), named DustArch1, which will contain two LVs (Logical Volumes) named root and swap containing the root filesystem and the swap respectively.

```
root@archiso ~ # pvcreate /dev/mapper/cryptroot
root@archiso ~ # vgcreate DustArch1 /dev/mapper/cryptroot
root@archiso ~ # lvcreate -L 100%FREE -n root DustArch1
root@archiso ~ # lvreduce -l -32G /dev/DustArch1/root
root@archiso ~ # lvcreate -L 100%FREE -n swap DustArch1
```

Format & mount

Now the only things left to do are formatting our freshly created logical volumes

```
root@archiso ~ # mkfs.ext4 -L / /dev/DustArch1/root
root@archiso ~ # mkswap /dev/DustArch1/swap
```

as well as mounting them and enabling the \mathtt{swap} , in order to proceed with the next steps.

```
root@archiso ~ # mount /dev/DustArch1/root /mnt
root@archiso ~ # mkdir /mnt/efi
root@archiso ~ # mount /dev/nvmeOn1p1 /mnt/efi
root@archiso ~ # swapon /dev/DustArch1/swap
```

Unmount & Close

WARNING: Only do this, after you're finished with your setup within the archiso and are about to boot into your system, or else the next steps won't work for you.

To close everything back up again,

1. unmount the volumes

```
root@archiso ~ # umount /mnt/efi /mnt
```

2. deactivate the VG

```
root@archiso ~ # vgchange -a n DustArch1
```

3. close the LUKS volume

```
root@archiso ~ # cryptsetup close cryptroot
```

1.3 Preparing the chroot environment

First it might make sense to edit /etc/pacman.d/mirrorlist to move the mirror(s) geographically closest to you to the top.

After that we can pacstrap the minimum packages needed. We will install all other packages later on.

NOTE: This is the actual command used in my case

```
root@archiso ~ # pacstrap /mnt base linux linux-firmware
```

After that generate an fstab using genfstab

```
root@archiso ~ # genfstab -U /mnt >> /mnt/etc/fstab
```

and you're ready to enter the chroot environment.

Chapter 2

Entering the chroot

NOTE: As we want to set up our new system, we need to have access to the different partitions, the internet, etc. which we wouldn't get by solely using chroot.

That's why we are using arch-chroot, provided by the arch-install-scripts package already shipped with the archiso. This script takes care of all that stuff, so we can set up our system properly.

```
root@archiso ~ # arch-chroot /mnt
```

Et Voila! You successfully chrooted inside your new system and you'll be greeted by a bash prompt.

2.1 Installing additional packages

core	amd-ucode base-devel diffutils dmraid dnsmasq dosfstools efi
extra	efitools git intel-ucode networkmanager networkmanager-op
community	neovim o

NOTE: There are many command line text editors available, like nano, vi, vim, emacs, etc.

I'll be using neovim, though it shouldn't matter what editor you choose.

Make sure to enable the NetworkManager.service service, in order for the Internet connection to work upon booting into our fresh system later on.

```
[root@archiso /]# systemctl enable NetworkManager.service
```

With polkit installed, create a file /etc/polkit-1/rules.d/50-org.freedesktop.Ne to enable users of the network group to add new networks without the need of sudo.

If you use UEFI, you'll also need the efibootmgr, in order to modify the UEFI entries.

2.2 Master of time

After that you have to set your timezone and update the system clock.

Generally speaking, you can find all the different timezones under /usr/share/zoneinfo In my case, my timezone resides under /usr/share/zoneinfo/Europe/Berlin.

To achieve the desired result, I want to symlink this to /etc/localtime and set the hardware clock.

Now you can also enable time synchronization over network

```
[root@archiso /]# timedatectl set-timezone Europe/Berlin
[root@archiso /]# timedatectl set-ntp true
```

and check that everything is alright

```
[root@archiso /]# timedatectl status
```

2.3 Master of locales

Now you have to generate your locale information.

For that you have to edit /etc/locale.gen and uncomment the locales you want to enable.

NOTE: I recommend to always uncomment en_US.UTF-8 UTF8, even if you want to use another language primarily.

In my case I only uncommented the en_US.UTF-8 UTF8 line

```
en_US.UTF-8 UTF8
```

After that you still have to actually generate the locales by issuing

```
[root@archiso /]# locale-gen
```

and set the locale

```
[root@archiso /]# localectl set-locale LANG="en_US.UTF-8"
```

After that we're done with this part.

2.4 Naming your machine

Now we can set the hostname and add hosts entries.

Apart from being mentioned in your command prompt, the hostname also serves the purpose of identifying, or naming your machine. This enables you to see your PC in your router, etc.

2.4.1 hostname

To change the $\verb|hostname|$, simply edit $\verb|/etc/hostname|$, enter the desired name, then save and quit.

I .	
D 1 A 1	
DustArch	
D dD oni Cii	

2.4.2 hosts

Now we need to specify some hosts entries by editing /etc/hosts

```
# Static table lookup for hostnames.
# See hosts(5) for details.

127.0.0.1 localhost .
::1 localhost .
127.0.1.1 DustArch.localhost DustArch
```

2.5 User setup

Now you should probably change the default root password and create a new non-root user for yourself, as using your new system purely through the native root user is not recommended from a security standpoint.

2.5.1 Give root a password

To change the password for the current user (the root user) issue

[root@archiso /]# passwd

and choose a new password.

2.5.2 Create a personal user

core	sudo
extra	zsh

We are going to create a new user and set the password, groups and shell for this user

We now have to allow the wheel group sudo access.

For that we edit /etc/sudoers and uncomment the %wheel line

```
%wheel ALL=(ALL) ALL
```

You could also add a new line below the root line

```
root ALL=(ALL) ALL
```

with your new username

```
dustvoice ALL=(ALL) ALL
```

to solely grant the new user sudo privileges.

2.6 Boot manager

In this section different boot managers are explained.

2.6.1 EFISTUB

core efibootmgr

You can directly load the kernel and the initramfs by using efibootmgr

```
[root@archiso /]# efibootmgr --disk /dev/sda --part 2

→ --create --label "Arch Linux" --loader /vmlinuz-linux

→ --unicode

→ 'root=6ff60fab-c046-47f2-848c-791fbc52df09 rw initrd=\initramfs-lin

→

--verbose
```

2.6.2 grub

tmgr grub
֡

Now onto installing the boot manager. We will use grub in this guide.

First make sure, all the required packages are installed

```
[root@archiso /]# pacman -S grub dosfstools os-prober mtools
```

and if you want to use UEFI, also

```
[root@archiso /]# pacman -S efibootmgr
```

BIOS

If you chose the BIOS - MBR variation, you'll have to do nothing special

If you chose the BIOS - GPT variation, you'll have to have a +1M boot partition created with the partition type set to BIOS boot.

In both cases you'll have to run the following comman now

```
[root@archiso /]# grub-install --target=i386-pc /dev/sdb
```

NOTE: It should obvious that you would need to replace <code>/dev/sdb</code> with the disk you actually want to use. Note however that you have to specify a <code>disk</code> and not a partition, so no number.

UEFI

If you chose the UEFI - GPT variation, you'll have to have the EFI System Partition mounted at /boot (where /dev/sda2 is the partition holding said EFI System Partition in my particular setup)

Now install grub to the EFI System Partition

```
[root@archiso /]# grub-install --target=x86_64-efi
    --efi-directory=/boot --bootloader-id=grub --recheck
```

IMPORTANT: If you've planned on dual booting arch with Windows and therefore reused the EFI System Partition created by Windows, you might not be able to boot to grub just yet.

In this case, boot into Windows, open a cmd window as Administrator and type in

```
bcdedit /set {bootmgr} path \EFI\grub\grubx64.efi
```

To make sure that the path is correct, you can use

```
[root@archiso /]# ls /boot/EFI/grub
```

under Linux to make sure, that the grubx64.efi file is really there.

grub config

In all cases, you now have to create the main grub.cfg configuration file.

But before we actually generate it, we'll make some changes to the default grub settings, which the grub.cfg will be generated from.

Adjust the timeout First of all, I want my grub menu to wait indefinitely for my command to boot an OS.

```
GRUB_TIMEOUT=-1
```

NOTE: I decided on this, because I'm dual booting with Windows and after Windows updates itself, I don't want to accidentally boot into my Arch Linux, just because I wasn't quick enough to select the Windows Boot Loader from the grub menu.

Of course you can set this parameter to whatever you want.

Another way of achieving what I described, would be to make grub remember the last selection.

```
GRUB_TIMEOUT=5
GRUB_DEFAULT=saved
GRUB_SAVEDEFAULT="true"
```

Enable the recovery After that I also want the recovery option showing up, which means that besides the standard and fallback images, also the recovery one would show up.

GRUB_DISABLE_RECOVERY=false

NVIDIA fix Now, as I'm using the binary NVIDIA driver for my graphics card, I also want to make sure, to revert grub back to text mode, after I select a boot entry, in order for the NVIDIA driver to work properly. You might not need this

GRUB_GFXPAYLOAD_LINUX=text

Add power options I also want to add two new menu entries, to enable me to shut down the PC, or reboot it, right from the grub menu.

```
menuentry '=> Shutdown' {
    halt
}
menuentry '=> Reboot' {
    reboot
}
```

Installing memtest As I want all possible options to possibly troubleshoot my PC right there in my grub menu, without the need to boot into a live OS, I also want to have a memory tester there.

For a BIOS setup, you'll simply need to install the memtest86+ package, with no further configuration.

For a UEFI setup, you'll first need to install the package and then tell memtest86-efi^{AUR} how to install itself

Now select option 3, to install it as a grub2 menu item.

Enabling hibernation We need to add the resume kernel parameter to /etc/default/grub, containing my swap partition UUID, in my case

```
J

→ GRUB_CMDLINE_LINUX_DEFAULT="loglevel=3 quiet resume=UUID=097c6f11-f
```

NOTE: If you have to change anything, like the swap partition UUID, inside the grub configuration files, you'll always have to rerun grub-mkconfig as explained in Generating the grub config.

Generating the grub config Now we can finally generate our grub.cfg

```
[root@archiso /]# grub-mkconfig -o /boot/grub/grub.cfg
```

Now you're good to boot into your new system.

2.7 Switch to a systemd based ramdisk

NOTE: There is nothing particularly better about using a systemd based ramdisk instead of a busybox one, it's just that I prefer it.

Some advantages, at least in my opinion, that the systemd based ramidsk has, are the included resume hook, as well as password caching, when decrypting encrypted volumes, which means that because I use the same LUKS password for both my data storage HDD, as well as my cryptroot, I only have to input the password once for my cryptroot and my data storage HDD will get decrypted too, without the need to create /etc/crypttab entries, etc.

To switch to a systemd based ramdisk, you will normally need to substitute the busybox specific hooks for systemd ones. You will also need to use systemd hooks from now on, for example sd-encrypt instead of encrypt.

• base

In my case, I left the base hook untouched, to get a busybox recovery shell, if something goes wrong, although you wouldn't technically need it, when using systemd.

WARNING: Don't remove this, when using busybox, unless you're absolutely knowing what you're doing.

udev

Replace this with systemd to switch from busybox to systemd.

• keymap and/or consolefont

These two, or one, if you didn't use one of them, need to be replaced with sd-vconsole. Everything else stays the same with these.

• encrypt

Isn't used in the default /etc/mkinitcpio.conf, but could be important later on, for example when using Full system encryption. You need to substitute this with sd-encrypt.

• lvm2

Same thing as with encrypt and needs to be substituted with sd-lvm2.

NOTE: You can find all purposes of the hooks, as well as the busybox/systemd equivalent of each one in the

ArchWiki.

2.8 Hibernation

In order to use the hibernation feature, you should make sure that your swap partition/file is at least the size of your RAM.

NOTE: If you use a busybox based ramdisk, you need to

1. add the resume hook to /etc/mkinitcpio.conf, before fsck and definetely after block

```
\rightarrow HOOKS=(base udev autodetect modconf block filesystems keyboard
```

2. run

```
[root@archiso /]# mkinitcpio -p linux
```

NOTE: When using EFISTUB without sbupdate, your motherboard has to support kernel parameters for boot entries. If your motherboard doesn't support this, you would need to use systemd-boot.

2.9 Secure Boot

2.9.1 shim

WARNING: This is a way of handling secure boot that aims at just making everything work!

It is not the way Secure Boot was intended to be used and you might as well disable it.

If you need Secure Boot to be enabled, e.g. for Windows, but you couldn't care less for the security it could bring to your device, use this method.

If you want to actually make use of the Secure Boot feature, read The manual way.

I know I told you that you're now good to boot into your new system. That is only correct, if you're **not** using Secure Boot.

You can either proceed by disabling Secure Boot in your firmware settings, or by using shim as kind of a pre-bootloader, as well as signing your bootloader (grub) and your kernel.

If you decided on using Secure Boot, you will first have to install the package.

Now we just need to copy shimx64.efi, as well as mmx64.efi to our EFI System Partition

```
[root@archiso /]# cp /usr/share/shim-signed/shimx64.efi

    /boot/EFI/grub/
[root@archiso /]# cp /usr/share/shim-signed/mmx64.efi
    /boot/EFI/grub/
```

NOTE: If you have to use bcdedit from within Windows, as explained previously, you need to adapt the command accordingly

```
bcdedit /set {bootmgr} path \EFI\grub\shimx64.efi
```

Now you will be greeted by MokManager everytime you update your bootloader or kernel.

Just choose Enroll hash from disk and enroll your bootloader (grubx64.efi) and kernel (vmlinuz-linux).

Reboot and your system should fire up just fine.

2.9.2 The manual way

WARNING: As this is a very tedious and time consuming process, it only makes sense when also utilizing some sort of disk encryption, which is, why I would advise you to read Full system encryption first.

File formats

In the following subsections, we will be dealing with some different file formats.

.key

PEM format private keys for EFI binary and EFI signature list signing.

.crt

PEM format certificates for sbsign.

.cer

DER format certifficates for firmware.

.esl

Certificates in EFI Signature List for KeyTool and/or firmware.

Create the keys

First off, we have to generate our Secure Boot keys.

These will be used to sign any binary which will be executed by the firwmare.

.auth

Certificates in EFI Signature List with authentication header (i.e. a signed certificate update file) for KeyTool and/or firmware. ${\tt GUID}$ Let's create a ${\tt GUID}$ first to use with the next commands.

[root@archiso ~/sb]# uuidgen --random > GUID.txt

PK We can now generate our PK (Platform Key)

```
[root@archiso ~/sb]# openssl req -newkey rsa:4096 -nodes

→ -keyout PK.key -new -x509 -sha256 -subj

→ "/CN=Platform Key for DustArch/" -out PK.crt
[root@archiso ~/sb]# openssl x509 -outform DER -in PK.crt

→ -out PK.cer
[root@archiso ~/sb]# cert-to-efi-sig-list -g "$(< GUID.txt)"

→ PK.crt PK.esl
[root@archiso ~/sb]# sign-efi-sig-list -g "$(< GUID.txt)" -k

→ PK.key -c PK.crt PK PK.esl PK.auth
```

In order to allow deletion of the PK, for firmwares which do not provide this functionality out of the box, we have to sign an empty file.

```
[root@archiso ~/sb]# sign-efi-sig-list -g "$(< GUID.txt)" -k

→ PK.key -c PK.crt PK /dev/null rm_PK.auth</pre>
```

KEK We proced in a similar fashion with the KEK (Key Exchange Key)

```
[root@archiso ~/sb]# openssl req -newkey rsa:4096 -nodes

→ -keyout KEK.key -new -x509 -sha256 -subj

→ "/CN=Key Exchange Key for DustArch/" -out KEK.crt
[root@archiso ~/sb]# openssl x509 -outform DER -in KEK.crt

→ -out KEK.cer
[root@archiso ~/sb]# cert-to-efi-sig-list -g "$(< GUID.txt)"

→ KEK.crt KEK.esl
[root@archiso ~/sb]# sign-efi-sig-list -g "$(< GUID.txt)" -k

→ PK.key -c PK.crt KEK KEK.esl KEK.auth
```

 ${\tt DB}$ $\,$ And finally the ${\tt DB}$ (Signature Database) key.

```
[root@archiso ~/sb] # openssl req -newkey rsa:4096 -nodes

→ -keyout db.key -new -x509 -sha256 -subj

→ "/CN=Signature Database key for DustArch" -out db.crt
[root@archiso ~/sb] # openssl x509 -outform DER -in db.crt

→ -out db.cer
[root@archiso ~/sb] # cert-to-efi-sig-list -g "$(< GUID.txt)"

→ db.crt db.esl
[root@archiso ~/sb] # sign-efi-sig-list -g "$(< GUID.txt)" -k

→ KEK.key -c KEK.crt db db.esl db.auth
```

Windows stuff

As your plan is to be able to control, which things do boot on your system and which don't, you're going through all this hassle to create and enroll custom keys, so only EFI binaries signed with said keys can be executed.

But what if you have a Windows dual boot setup?

Well the procedure is actually pretty straight forward. You just grab Microsoft's certificates, convert them into a usable format, sign them and enroll them. No need to sign the Windows boot loader.

```
[root@archiso ~/sb]# curl -fLo WinCert.crt https://www.micro

→ soft.com/pkiops/certs/MicWinProPCA2011_2011-10-19.crt
[root@archiso ~/sb]# openssl x509 -inform DER -outform PEM

→ -in MicWinCert.crt -out MicWinCert.pem
[root@archiso ~/sb]# cert-to-efi-sig-list -g

→ 77fa9abd-0359-4d32-bd60-28f4e78f784b MicWinCert.pem

→ MS_db.esl
[root@archiso ~/sb]# sign-efi-sig-list -a -g

→ 77fa9abd-0359-4d32-bd60-28f4e78f784b -k KEK.key -c

→ KEK.crt db MS_db.esl add_MS_db.auth
```

Move the kernel & keys

In order to ensure a smooth operation, with actual security, we need to move some stuff around.

Kernel, initramfs, microcode pacman

will put its unsigned and unencrypted kernel, initramfs and microcode images into /boot, which is, why it will be no longer a good idea, to leave your EFI System Partition mounted there. Instead we will create a new mount point under /efi and modify our fstab accordingly.

Keys As you probably want to automate signing sooner or later and only use the ultimately necessary keys for this process, as well as store the other more important keys somewhere more safe and secure than your root home directory, we will move the necessary keys.

I personally like to create a /etc/efi-keys directory, chmodded to 700 and place my db.crt and db.key there. All the keys will get packed into a tar archive and encrypted with a strong symmetric pass phrase and stored somewhere secure and safe.

Signing

Signing is the process of, well, signing your EFI binaries, in order for them to be allowed to be executed, by the motherboard firmware. At the end of the day, that's why you're doing all this, to prevent an attack by launching unknown code.

Manual signing Of course, you can sign images yourself manually. In my case, I used this, to sign the boot loader, kernel and initramfs of my USB installation of Arch Linux.

NOTE: As always, manual signing also comes with its caveats!

If I update my kernel, boot loader, or create an updated initramfs on my Arch Linux USB installation, I have to sign those files again, in order to be able to boot it on my PC.

Of course you can always script and automate stuff, but if you want something more easy for day to day use, I really recommend that you try out sbupdate, which I will explain in the next section sbupdate.

For example, if I want to sign the kernel image of my USB installation, where I mounted the boot partition to/mnt/dustarchusb/boot, I would have to do the following

```
[root@archiso ~/sb]# sbsign --key /etc/efi-keys/db.key
    --cert /etc/efi-keys/db.crt --output /boot/vmlinuz-linux
    /boot/vmlinuz-linux
```

AUR sbupdate-git

Of course, if you're using Secure Boot productively, you would want something more practical than manual signing, especially since you need to sign

- the boot loader
- the kernel image
- the initramfs

Fortunately there is an easy and uncomplicated tool out there, that does all that for you, called sbupdate.

It not only signs everything and also foreign EFI binaries, if specified, but also combines your kernel and initramfs into a single executable EFI binary, so you don't even need a boot loader, if your motherboard implementation supports booting those.

After installing sbupdate, we can edit the /etc/sbupdate.conf file, to set everything up.

Everything in this config should be self-explanatory.

You will probably need to

- set ESP_DIR to /efi
- add any other EFI binary you want to have signed to EXTRA_SIGN
- add your kernel parameters, for example rd.luks.name, root, rw, resume, etc. to CMDLINE_DEFAULT

After you've successfully configured sbupdate, you can run it as root, to create all the signed files.

NOTE: sbupdate will be executed upon kernel updates by pacman, but not if you change your initramfs with something like mkinitcpio. In that case you will have to run sbupdate manually.

Add EFI entries

core efibootmgr

Now the only thing left to do, if you want to stay boot loader free anyways, is to add the signed images to the boot list of your NVRAM. You can do this with efibootmgr.

```
[root@archiso ~/sb]# efibootmgr -c -d /dev/nvmeOn1 -p 1 -L

→ "Arch Linux fallback" -l

→ "EFI\Arch\linux-fallback-signed.efi
[root@archiso ~/sb]#

→ efibootmgr -c -d /dev/nvmeOn1 -p 1 -L "Arch Linux

→ " -l "EFI\Arch\linux-signed.efi
```

Of course you can extend this list, with whichever entries you need.

Enrolling everything

First off, copy all .cer, .esl and .auth files to a FAT formatted filesystem. I'm using my EFI System Partition for this.

After that reboot into the firmware setup of your motherboard, clear the existing Platform Key, to set the firmware into "Setup Mode" and enroll the db, KEK and PK certificates in sequence.

NOTE: Enroll the Platform Key last, as it sets most firmware's Secure Boot sections back into "User mode", exiting "Setup Mode".

Chapter 3

Inside the DustArch

This section helps at setting up the customized system from within an installed system.

This section mainly provides aid with the basic set up tasks, like networking, dotfiles, etc.

 ${\bf NOTE} :$ Not everything in this section is mandatory.

This section is rather a guideline, because it is easy to forget some steps needed, for example jack for audio production, that only become apparent, when they're needed.

It is furthermore the responsibility of the reader to decide which steps to skip and which need further research. As I mentioned, this is only a guide and not the answer to everything.

3.1 Someone there?

First we have to check if the network interfaces are set up properly.

To view the network interfaces with all their properties, we can issue

```
DustArch% ip link
```

To make sure that you have a working *Internet* connection, issue

```
DustArch% ping archlinux.org
```

Everything should run smoothly if you have a wired connection.

If there is no connection and you're indeed using a wired connection, try restarting the NetworkManager service

```
\verb"DustArch", sudo systemctl restart Network Manager.service"
```

and then try pinging again.

If you're trying to utilize a Wi-Fi connection, use nmcli, the NetworkManager's command line tool, or nmtui, the NetworkManager terminal user interface, to connect to a Wi-Fi network.

NOTE: I never got nmtui to behave like I wanted it to, in my particular case at least, which is the reason why I use nmcli or the GUI tools.

First make sure, the scanning of nearby Wi-Fi networks is enabled for your Wi-Fi device

```
DustArch% nmcli radio
```

and if not, enable it

```
DustArch% nmcli radio wifi on
```

DustArch% nmcli device

Rescan for available networks

DustArch% nmcli device wifi rescan

and list all found networks

DustArch% nmcli device wifi list

After that connect to the network

DustArch% nmcli device wifi connect --ask

Now try pinging again.

3.2 Update and upgrade

After making sure that you have a working Internet connection, you can then proceed to update and upgrade all installed packages by issuing

DustArch% sudo pacman -Syu

3.3 Enabling the multilib repository

In order to make 32-bit packages available to pacman, we'll need to enable the multilib repository in /etc/pacman.conf first. Simply uncomment

and update pacman's package repositories afterwards

DustArch% sudo pacman -Syu

3.4 zsh for president

Of course you can use any shell you want. In my case I'll be using the zsh shell.

NOTE: I am using **zsh** because of its auto completion functionality and extensibility, as well as a brilliant **vim** like navigation implementation through a plugin, though that might not be what you're looking for.

We already set the correct shell for the dustvoice user in the Create a personal user step, but I want to use zsh for the root user too, so I'll have to change root's default shell to it.

DustArch% sudo chsh -s /usr/bin/zsh root

Don't worry about the looks by the way, we're gonna change all that in just a second.

3.5 git

extra git

Install the package and you're good to go for now, as we'll care about the <code>.gitconfig</code> in just a second.

3.6 Security is important

core	gnupg
	0

If you've followed the tutorial using a recent version of the archiso, you'll probably already have the most recent version of gnupg installed by default.

3.6.1 Smartcard shenanigans

extra	libusb-compat	
community	ccid opensc pcsclite	

After that you'll still have to setup gnupg correctly. In my case I have my private keys stored on a smartcard.

To use it, I'll have to install the listed packages and then enable and start the pcscd service

```
DustArch% sudo systemctl enable pcscd.service
DustArch% sudo systemctl start pcscd.service
```

After that, you should be able to see your smartcard being detected

```
DustArch% gpg --card-status
```

NOTE: If your smartcard still isn't detected, try logging off completely or even restarting, as that sometimes is the solution to the problem.

3.7 Additional required tools

core	make openssh	
extra	clang cmake jdk-openjdk python	
community	pass python-pynvim	

To minimize the effort required by the following steps, we'll install most of the required packages beforehand

This will ensure, we proceed through the following section without the need for interruption, because a package needs to be installed, so the following content can be condensed to the relevant informations.

3.8 Setting up a home environment

In this step we're going to setup a home environment for both the root and my personal dustvoice user.

NOTE: In my case these 2 home environments are mostly equivalent, which is why I'll execute the following commands as the **dustvoice** user first and then switch to the **root** user and repeat the same commands.

I decided on this, as I want to edit files with elevated permissions and still have the same editor style and functions/plugins.

Note that this comes with some drawbacks. For example, if I change a configuration for my dustvoice user, I would have to regularly update it for the root user too. This bears the problem, that I have to register my smartcard for the root user. This in turn is problematic, cause the gpg-agent used for ssh authentication, doesn't behave well when used within a su or sudo -i session. So in order to update root's config files I would either need to symlink everything, which I won't do, or I'll need to login as the root user now and then, to update everything.

NOTE: In my case, I want to access all my git repositories with my gpg key on my smartcard. For that I have to configure the gpg-agent with some configuration files that reside in a git repository. This means I will have to reside to using the https URL of the repository first and later changing the URL either in the corresponding .git/config file, or by issuing the appropriate command.

3.8.1 Use dotfiles for a base config

To provide myself with a base configuration, which I can then extend, I have created a dotfiles repository, which contains all kinds of configurations.

The special thing about this dotfiles repository is that it is my home folder. By using a curated .gitignore file, I'm able to only include the configuration files I want to keep between installs into the repository and ignore everything else.

To achieve this very specific setup, I have to turn my home directory into said dotfiles repository first

```
DustArch% git init

J

→ DustArch% git remote add origin https://git.dustvoice.de/DustVoice/
DustArch% git fetch

DustArch% git reset origin/master --hard

DustArch% git branch --set-upstream-to=origin/master master
```

Now I can issue any git command in my directory, because it now is a git repository.

3.8.2 Set up gpg

As I wanted to keep my dotfiles repository as modular as possible, I utilize git's submodule feature. Furthermore I want to use my nvim repository, which contains all my configurations and plugins for neovim, on Windows, but without all the Linux specific configuration files. I am also using the Pass repository on my Android phone and Windows PC, where I only need this repository without the other Linux configuration files.

Before we'll be able to update the submodules (nvim config files and passwordstore) though, we will have to setup our gpg key as an ssh key, as I use it to authenticate

```
dustvoice@DustArch ~
$ chmod 700 .gnupg
dustvoice@DustArch ~
$ gpg --card-status
dustvoice@DustArch ~
$ gpg --card-edit
```

```
(insert) gpg/card> fetch
(insert) gpg/card> q
```

```
dustvoice@DustArch ~
$ gpg-connect-agent updatestartuptty /bye
```

NOTE: You would have to adapt the keygrip present in the /.gnupg/sshcontrol file to your specific keygrip, retrieved with gpg -K --with-keygrip.

Now, as mentioned before, I'll switch to using **ssh** for authentication, rather than https

```
dustvoice@DustArch ~
$ git remote set-url origin

→ git@git.dustvoice.de:DustVoice/dotfiles.git
```

As the best method to both make zsh recognize all the configuration changes, as well as the gpg-agent behave properly, is to re-login, we'll do just that

dustvoice@DustArch ~

\$ exit

WARNING: It is very important to note, that I mean a real re-login.

That means that if you've used ssh to log into your machine, it probably won't be sufficient to login into a new ssh session. You'll probably need to restart the machine completely.

3.8.3 Finalize the dotfiles

Now log back in and continue

```
dustvoice@DustArch ~
$ git submodule update --recursive --init
dustvoice@DustArch ~
$ source .zshrc
dustvoice@DustArch ~
$ cd .config/nvim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:platform = "linux"' >> platform.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_autocomplete = 3' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_clang_format = 1' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_font = 0' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ nvim --headless +PlugInstall +qa
dustvoice@DustArch ~/.config/nvim
$ cd plugged/YouCompleteMe
dustvoice@DustArch ~/.config/nvim/plugged/YouCompleteMe
$ python3 install.py --clang-completer --java-completer
dustvoice@DustArch ~/.config/nvim/plugged/YouCompleteMe
$ cd ~
```

3.8.4 gpg-agent forwarding

Now there is only one thing left to do, in order to make the gpg setup complete: gpg-agent forwarding over ssh. This is very important for me, as I want to use my smartcard on my development server too, which requires me, to forward/tunnel my gpg-agent to my remote machine.

First of all, I want to setup a config file for ssh, as I don't want to pass all parameters manually to ssh every time.

NOTE: You would of course, need to adapt the content in between the < and > brackets.

To get the paths needed as parameters for RemoteForward, issue

```
dustvoice@DustArch ~
$ gpgconf --list-dirs
```

Example 1. An example for a valid /.ssh/config would be

```
Host archserver

HostName pc.dustvoice.de

ForwardAgent yes

ForwardX11 yes

RemoteForward /run/user/1000/gnupg/S.gpg-agent /run/user/1000/g

RemoteForward /run/user/1000/gnupg/S.gpg-agent.ssh /
```

Now you'll still need to enable some settings on the remote machine(s).

StreamLocalBindUnlink yes AllowAgentForwarding yes X11Forwarding yes

Now just restart your remote machine(s) and you're ready to go.

NOTE: If you use alacritty, to connect to your remote machine over ssh, you will need to install the alacritty on the remote machine too, as alacritty uses its own \$TERM.

Another option would be changing that variable for the ssh command

dustvoice@DustArch ~

\$ TERM=xterm-256colors ssh remote-machine

3.8.5 Back to your roots

As mentioned before, you would now switch to the root user, either by logging in as root, or by using

```
dustvoice@DustArch ~
$ sudo -iu root
```

Now go back to Setting up a home environment to repeat all commands for the root user.

WARNING: A native login would be better compared to sudo -iu root, as there could be some complications, like already running gpg-agent instances, etc., which you would need to manually resolve, when using sudo -iu root.

3.9 Audio

Well, why wouldn't you want audio...

3.9.1 alsa

extra	alsa-utils
-------	------------

NOTE: You're probably better off using pulseaudio and/or jack.

Now choose the sound card you want to use

```
dustvoice@DustArch ~
$ cat /proc/asound/cards
```

and then create /etc/asound.conf

```
defaults.pcm.card 2
defaults.ctl.card 2
```

NOTE: It should be apparent, that you would have to switch out 2 with the number corresponding to the sound card you want to use.

3.9.2 pulseaudio

extra	pavucontrol pulseaudio
community	pulsemixer

Some applications require pulseaudio, or work better with it, for example discord, so it might make sense to use pulseaudio

For enabling real-time priority for pulseaudio on Arch Linux, please make sure your user is part of the audio group and edit the file /etc/pulse/daemon.conf, so that you uncomment the lines

```
high-priority = yes
nice-level = -11
realtime-scheduling = yes
realtime-priority = 5
```

If your system can handle the load, you can also increase the remixing quality, by changing the resample-method

```
resample-method = speex-float-10
```

Of course a restart of the pulseaudio daemon is necessary to reflect the changes you just made

```
dustvoice@DustArch ~
$ pulseaudio --kill
dustvoice@DustArch ~
$ pulseaudio --start
```

3.9.3 jack

extra	pulseaudio-jack
community	cadence jack2

If you either want to manually control audio routing, or if you use some kind of audio application like ardour, you'll probably want to use jack and cadence as a GUI to control it, as it has native support for bridging pulseaudio to jack.

3.9.4 Audio handling

extra	libao libid3tag libmad libpulse opus wavpack
community	sox twolame

To also play audio, we need to install the mentioned packages and then simply do $\,$

```
dustvoice@DustArch ~
$ play audio.wav
dustvoice@DustArch ~
$ play audio.mp3
```

to play audio.

3.10 Bluetooth

extra	bluez bluez-util pulseaudio-bluetooth	
community	blueman	

To set up Bluetooth, we need to install the bluez and bluez-utils packages in order to have at least a command line utility bluetoothctl to configure connections

Now we need to check if the btusb kernel module was already loaded

```
dustvoice@DustArch ~
$ sudo lsmod | grep btusb
```

After that we can enable and start the bluetooth.service service

```
dustvoice@DustArch ~
$ sudo systemctl enable bluetooth.service
dustvoice@DustArch ~
$ sudo systemctl start bluetooth.service
```

NOTE: To use bluetoothctl and get access to the Bluetooth device of your PC, your user needs to be a member of the lp group.

Now simply enter bluetoothctl

```
dustvoice@DustArch ~
$ bluetoothctl
```

In most cases your Bluetooth interface will be preselected and defaulted, but in some cases, you might need to first select the Bluetooth controller

```
(insert) [DustVoice]# list
(insert) [DustVoice]# select <MAC_address>
```

After that, power on the controller

```
(insert) [DustVoice]# power on
```

Now enter device discovery mode

```
(insert) [DustVoice]# scan on
```

and list found devices

```
(insert) [DustVoice]# devices
```

NOTE: You can turn device discovery mode off again, after your desired device has been found

```
(insert) [DustVoice]# scan off
```

Now turn on the agent

```
(insert) [DustVoice]# agent on
```

and pair with your device

```
(insert) [DustVoice]# pair <MAC_address>
```

NOTE: If your device doesn't support PIN verification you might need to manually trust the device

```
(insert) [DustVoice]# trust <MAC_address>
```

Finally connect to your device

```
(insert) [DustVoice]# connect <MAC_address>
```

NOTE: If your device is an audio device, of some kind you might have to install pulseaudio-bluetooth and append 2 lines to /etc/pulse/system.pa as well.

append the following 2 lines

```
load-module module-bluetooth-policy
load-module module-bluetooth-discover
```

and restart pulseaudio

```
dustvoice@DustArch ~
$ pulseaudo --kill
dustvoice@DustArch ~
$ pulseaudo --start
```

If you want a GUI to do all of this, just install blueman and launch blueman-manager

3.11 Graphical desktop environment

extra	ttf-hack xclip xorg xorg-drivers xorg-xinit	
community	arandr alacritty bspwm dmenu sxhkd	
AUR	polybar	

If you decide, that you want to use a graphical desktop environment, you have to install additional packages in order for that to work.

NOTE: xclip is useful, when you want to send something to the X clipboard. It is also required, in order for neovim's clipboard to work correctly. It is not required though.

3.11.1 NVIDIA

extra | nvidia nvidia-utils nvidia-settings opencl-nvidia

If you also want to utilize special NVIDIA functionality, for example for davinci-resolve, you'll most likely need to install their proprietary driver.

To configure the X server correctly, one can use nvidia-xconfig

```
dustvoice@DustArch ~
$ sudo nvidia-xconfig
```

If you want to further tweak all settings available, you can use nvidia-settings.

```
dustvoice@DustArch ~
$ sudo nvidia-settings
```

will enable you to "Save to X Configuration File", witch merges your changes with /etc/X11/xorg.conf.

With

```
dustvoice@DustArch ~
$ nvidia-settings
```

you'll only be able to save the current configuration to $\mbox{/.nvidia-settings-rc}$, witch you have to source after X startup with

```
dustvoice@DustArch ~
$ nvidia-settings --load-config-only
```

NOTE: You will have to reboot sooner or later after installing the NVIDIA drivers, so you might as well do it now, before any complications come up.

3.11.2 Launching the graphical environment

After that you can now do startx in order to launch the graphical environment.

If anything goes wrong in the process, remember that you can press Ctrl+Alt+<Number to switch ttys.

The NVIDIA way

community	bbswitch
AUR	nvidia-xrun

If you're using an NVIDIA graphics card, you might want to use nvidia-xrun^{AUR} instead of startx. This has the advantage, of the nvidia kernel modules, as well as the nouveau ones not loaded at boot time, thus saving power. nvidia-xrun^{AUR} will then load the correct kernel modules and run the .nvidia-xinitrc script in your home directory (for more file locations look into the documentation for nvidia-xrun^{AUR}).

IMPORTANT: At the time of writing, nvidia-xrun^{AUR} needs sudo permissions before executing its task.

NOTE:

AUR	nvidia-xrun-pm

If your hardware doesn't support bbswitch, you would need to use nvidia-xrun-pm^{AUR} instead.

Now we need to blacklist **both nouveau and nvidia** kernel modules.

To do that, we first have to find out, where our active modprobe.d directory is located. There are 2 possible locations, generally speaking: /etc/modprobe.d and /usr/lib/modprobe.d. In my case it was the latter, which I could tell, because this directory already had files in it.

Now I'll create a new file named nvidia-xrun.conf and write the following into it

blacklist nvidia
blacklist nvidia-drm
blacklist nvidia-modeset
blacklist nvidia-uvm
blacklist nouveau

With this config in place,

dustvoice@DustArch ~

```
$ lsmod | grep nvidia
```

and

```
dustvoice@DustArch ~
$ lsmod | grep nouveau
```

should return no output. Else you might have to place some additional entries into the file.

NOTE: Of course, you'll need to reboot, after blacklisting the modules and before issuing the 2 commands mentioned.

NOTE: If you installed nvidia-xrun-pm instead of nvidia-xrun and bbswitch, you might want to also enable the nvidia-xrun-pm service

```
dustvoice@dustArch ~
$ sudo systemctl enable nvidia-xrun-pm.service
```

NOTE: The required .nvidia-xinitrc file, mentioned previously, should already be provided in the dotfiles repository.

Now instead of startx, just run nvidia-xrun, enter your sudo password and you're good to go.

3.12 Additional console software

Software that is useful in combination with a console.

3.12.1 tmux

community tmux

I would reccommend to install tmux which enables you to have multiple terminal instances (called windows in tmux) open at the same time. This makes working with the linux terminal much easier.

 $\bf NOTE:$ To view a list of keybinds, you just need to press CTRL+b followed by ?.

3.12.2 Communication

Life is all about communicating. Here are some pieces of software to do exactly that.

```
community weechat
```

weechat is an IRC client for the terminal, with the best features and even a vim mode, by using a plugin

To configure everything, open weechat

```
dustvoice@DustArch ~
$ weechat
```

and install vimode, as well as configure it

```
/script install vimode.py
/vimode bind_keys

J

→ /set plugins.var.python.vimode.mode_indicator_normal_color_bg "blue
```

Now add mode_indicator+ in front of and ,[vi_buffer] to the end of weechat.bar.input.items, in my case

```
J

→ /set weechat.bar.input.items "mode_indicator+[input_prompt]+(away),
```

Now add ,cmd_completion to the end of weechat.bar.status.items, in my case

```
J

→ /set weechat.bar.status.items "[time],[buffer_last_number],[buffer_
```

Now enable vimode searching

```
/set plugins.var.python.vimode.search_vim on
```

Now you just need to add a new connection, for example irc.freenode.net

/server add freenode irc.freenode.net

and connect to it

/connect freenode

NOTE: You might need to authenticate with NickServ, before being able to write in a channel

/msg NickServ identify <password>

 ${\bf NOTE} :$ Instead of directly /setting the values specified above, you can also do

/fset weechat.var.name

select the entry you want to modify (for example for plugins.var.python.vimode) and then press s (make sure you're in insert mode) and Return, in order to modify the existing value.

3.12.3 PDF viewer

extra	ghostscript
community	fbida

To use asciidoctor-pdf, you might be wondering how you are supposed to open the generated PDFs from the native linux console.

This fbida package provides the fbgs software, which renders a PDF document using the native framebuffer.

To view this PDF document (Documentation.pdf) for example, you would run

dustvoice@DustArch ~
\$ fbgs Documentation.pdf

NOTE: You can view all the controls by pressing h.

3.13 Additional hybrid software

Some additional software providing some kind of \mathtt{GUI} to work with, but that can be useful in a $\mathtt{console}$ only environment nevertheless.

3.13.1 Password management

I'm using pass as my password manager. As we already installed it in the Additional required tools step and updated the submodule that holds our .password-store, there is nothing left to do in this step

3.13.2 python

extra	python
-------	--------

Python has become really important for a magnitude of use cases.

3.13.3 ruby & asciidoctor

extra ruby rubygems

In order to use asciidoctor, we have to install ruby and rubygems. After that we can install asciidoctor and all its required gems.

NOTE: If you want to have pretty and highlighted source code, you'll need to install a code formatter too.

For me there are mainly two options

• pygments.rb, which requires python to be installed

```
dustvoice@DustArch ~
$ gem install pygments.rb
```

• rouge which is a native ruby gem

```
dustvoice@DustArch ~
$ gem install rouge
```

Now the only thing left, in my case at least, is adding /.gem/ruby/2.7.0/bin to your path.

NOTE: Please note that if you run a ruby version different from 2.7.0, or if you upgrade your ruby version, you have to use the bin path for that version.

For zsh you'll want to add a new entry inside the .zshpath file

```
path+=("$HOME/.gem/ruby/2.7.0/bin")
```

which then gets sourced by the provided .zshenv file. An example is provided with the .zshpath.example file

NOTE: You might have to re-source the .zshenv file to make the changes take effect immediately

```
dustvoice@DustArch ~
$ source .zshenv
```

NOTE: If you want to add a new entry to the path variable, you have to append it to the array

```
path+=("pass:[$HOME/.gem/ruby/2.7.0/bin" "$

→ ]HOME/.gem/ruby/2.6.0/bin")
```

 ${f NOTE}$: If you use another shell than ${f zsh}$, you might have to do something different, to add a directory to your PATH.

3.13.4 JUCE and FRUT

 ${\tt JUCE}$ is a header only library for C++ that enables you to develop cross-platform applications with a single codebase.

FRUT makes it possible to manage JUCE projects purely from cmake.

```
dustvoice@DustArch ~
$ git clone https://github.com/WeAreROLI/JUCE.git
dustvoice@DustArch ~
$ cd JUCE
dustvoice@DustArch ~/JUCE
$ git checkout develop
dustvoice@DustArch ~/JUCE
$ cd ..
dustvoice@DustArch ~
$ git clone https://github.com/McMartin/FRUT.git
```

Using JUCE

	core	gcc gnutls
	extra	alsa-lib clang freeglut freetype2 ladspa libx11 libxcomposit
	community	jack2 libcurl-gnutls
İ	multilib	lib32-freeglut
	community	jack2 libcurl-gnutl

In order to use JUCE, you'll need to have some dependency packages installed, where ladspa and lib32-freeglut are not neccessarily needed.

3.13.5 Additional development tools

Here are just some examples of development tools one could install in addition to what we already have.

Code formatting

community	astyle
-----------	--------

We already have clang-format as a code formatter, but this only works for C-family languages. For java stuff, we can use astyle

Documentation

|--|

To generate a documentation from source code, I mostly use doxygen

Build tools

community ninja

In addition to make, I'll often times use ninja for my builds

3.13.6 Android file transfer

extra gvfs-mtp libmtp

Now you should be able to see your phone inside either your preferred filem-anager, in my case thunar, or ${\tt gigolo}^{\tt AUR}$.

If you want to access the android's file system from the command line, you will need to either install and use $simple-mtpfs^{AUR}$, or adb

${\tt simple-mtpfs^{AUR}}$

Edit /etc/fuse.conf to uncomment

```
user_allow_other
```

and mount the android device

```
dustvoice@DustArch ~
$ simple-mtpfs -l
dustvoice@DustArch ~
$ mkdir ~/mnt
dustvoice@DustArch ~
$ simple-mtpfs --device <number> ~/mnt -allow_other
```

and respectively unmount it

```
dustvoice@DustArch ~
$ fusermount -u mnt
dustvoice@DustArch ~
$ rmdir mnt
```

community | android-tools

Kill the adb server, if it is running

```
dustvoice@DustArch ~
$ adb kill-server
```

NOTE: If the server is currently not running, adb will output an error with a Connection refused message.

Now connect your phone, unlock it and start the adb server

```
dustvoice@DustArch ~
$ adb start-server
```

If the PC is unknown to the android device, it will display a confirmation dialog. Accept it and ensure that the device was recognized

```
dustvoice@DustArch ~
$ adb devices
```

Now you can push/pull files.

```
dustvoice@DustArch ~
$ adb pull /storage/emulated/0/DCIM/Camera/IMG.jpg .
dustvoice@DustArch ~
$ adb push IMG.jpg /storage/emulated/0/DCIM/Camera/IMG2.jpg
dustvoice@DustArch ~
$ adb kill-server
```

NOTE: Of course you would need to have the *developer options* unlocked, as well as the *USB debugging* option enabled within them, for adb to even work.

3.13.7 Partition management

extra	gparted	parted
	0000000	P

You may also choose to use a graphical partitioning software instead of fdisk or cfdisk. For that you can use gparted. Of course there is also the console equivalent 'parted.

3.13.8 PDF viewer

extra	evince	
community	zathura zathura-pdf-mupdf	

To use asciidoctor-pdf, you might be wondering how you are supposed to open the generated PDFs using the GUI.

zathura has a minimalistic design and UI with a focus on vim keybinding, whereas evince is a more desktop like experience, with things like a print dialogue, etc.

3.13.9 Process management

extra htop xfce4-taskmar	nager
--------------------------	-------

The native tool is top.

The next evolutionary step would be htop, which is an improved version of top (like vi and vim for example)

If you prefer a GUI for that kind of task, use xfce4-taskmanager.

3.13.10 Video software

Just some additional software related to videos.

Live streaming a terminal session

community tmate

For this task, you'll need a program called tmate.

3.14 Additional GUI software

As you now have a working graphical desktop environment, you might want to install some software to utilize your newly gained power.

3.14.1 Session Lock

community	xsecurelock	xss-lock
-----------	-------------	----------

Probably the first thing you'll want to set up is a session locker, which locks your X-session after resuming from sleep, hibernation, etc. It then requires you to input your password again, so no unauthorized user can access you machine.

I'll use xss-lock to hook into the necessary systemd events and xsecurelock as my locker.

NOTE: I have placed the required command to start xss-lock with the right parameters inside my bspwm configuration file.

If you use something other than \mathtt{bspwm} , you need to make sure this command gets executed upon start of the $\mathtt{X}\text{-session}$

```
xss-lock -l -- xsecurelock &
```

3.14.2 xfce-polkit AUR

AUR xfce-polkit

In order for GUI applications to acquire sudo permissions, we need to install a PolicyKit authentication agent.

We could use gnome-polkit for that purpose, which resides inside the official repositories, but I decided on using xfce-polkit^{AUR}.

Now you just need to startup $xfce-polkit^{AUR}$ before trying to execute something like gparted and you'll be prompted for your password.

As I already launch it as a part of my bspwm configuration, I won't have to worry about that.

3.14.3 Desktop background

extra nitrogen

You might want to consider installing nitrogen, in order to be able to set a background image

3.14.4 Compositing software

community picom

To get buttery smooth animation as well as e.g. smooth video playback in brave without screen tearing, you might want to consider using a compositor, in my case one named picom

WARNING: In order for obs' screen capture to work correctly, you need to kill picom completely before using obs.

```
dustvoice@DustArch ~ $ killall picom
```

or

```
dustvoice@DustArch ~
$ ps aux | grep picom
dustvoice@DustArch ~
$ kill -9 <pid>
```

3.14.5 networkmanager applet

extra	network-manager-applet
-------	------------------------

To install the NetworkManager applet, which lives in your tray and provides you with a quick method to connect to different networks, you have to install the network-manager-applet package

Now you can start the applet with

```
dustvoice@DustArch ~
$ nm-applet &
```

If you want to edit the network connections with a more full screen approach, you can also launch nm-connection-editor.

NOTE: The nm-connection-editor doesn't search for available Wi-Fis. You would have to set up a Wi-Fi connection completely by hand, which could be desirable depending on how difficult to set up your Wi-Fi is.

3.14.6 Show keyboard layout

AUR xkblayout-state

To show, which keyboard layout and variant is currently in use, you can use ${\tt xkblayout-state}^{\tt AUR}$

Now simply issue the layout alias, provided by my custom zsh configuration.

3.14.7 X clipboard

extra xclip

To copy something from the terminal to the xorg clipboard, use xclip

3.14.8 Taking screen shots

community scrot

For this functionality, especially in combination with rofi, use scrot scrot /Pictures/filename.png then saves the screen shot under /Pictures/filen

3.14.9 Image viewer

extra ristretto

Now that we can create screen shots, we might also want to view those

dustvoice@DustArch ~
\$ ristretto filename.png

3.14.10 File manager

extra	gvfs thunar
AUR	gigolo

You probably also want to use a file manager. In my case, thunar, the xfce file manager, worked best.

To also be able to mount removable drives, without being root or using sudo, and in order to have a GUI for mounting stuff, you would need to use gigolo^{AUR} and gvfs.

3.14.11 Archive manager

extra	cpio unrar unzip zip	
community	xarchiver	

As we now have a file manager, it might be annoying, to open up a terminal every time you simply want to extract an archive of some sort. That's why we'll use xarchiver.

3.14.12 Web browser

extra	firefox firefox-i18n-en-us
community	browserpass

As you're already using a GUI, you also might be interested in a web browser. In my case, I'm using firefox, as well as browserpass from the official repositories, together with the uBlock Origin, Dark Reader, DuckDuckGo Pricacy Essentials, Vimium and finally Browserpass add-ons, in order to use my passwords in brave and have best protection in regard to privacy, while browsing the web.

We still have to setup browserpass, after installing all of this

```
dustvoice@DustArch ~
$ cd /usr/lib/browserpass
dustvoice@DustArch /usr/lib/browserpass
$ make hosts-firefox-user
dustvoice@DustArch /usr/lib/browserpass
$ cd ~
```

Entering the dark side

AUR	tor-browser
-----	-------------

You might want to be completely anonymous whilst browsing the web at some point. Although this shouldn't be your only precaution, using ${\tt tor-browser^{AUR}}$ would be the first thing to do

 $\bf NOTE:$ You might have to check out how to import the gpg keys on the AUR page of tor-browser.

3.14.13 Office utilities

extra libreoffice-fresh

I'll use libreoffice-fresh for anything that I'm not able to do with neovim.

Printing

```
extra avahi cups cups-pdf nss-mdns print-manager system-config-printer
```

In order to be able to print from the gtk print dialog, we'll also need system-config-pri and print-manager.

```
dustvoice@DustArch ~
$ sudo systemctl enable avahi-daemon.service
dustvoice@DustArch ~
$ sudo systemctl start avahi-daemon.service
```

Now you have to edit /etc/nsswitch.conf and add mdns4_minimal [NOTFOUND=returned]

```
J

→ hosts: files mymachines myhostname mdns4_minimal [NOTFOUND=return]
```

Now continue with this

```
dustvoice@DustArch ~

$ avahi-browse --all --ignore-local --resolve --terminate dustvoice@DustArch ~

$ sudo systemctl enable org.cups.cupsd.service dustvoice@DustArch ~

$ sudo systemctl start org.cups.cupsd.service
```

Just open up system-config-printer now and configure your printer.

To test if everything is working, you could open up brave, then go to **Print** and then try printing.

3.14.14 Communication

Life is all about communicating. Here are some pieces of software to do exactly that.

Email

extra thunderbird	underbi	extra
-------------------	---------	-------

There is nothing better than some classical email.

Telegram

community	telegram-desktop
-----------	------------------

You want to have your telegram messages on your desktop PC?

${\bf TeamSpeak~3}$

community teamspeak3

Wanna chat with your gaming friends and they have a teamspeak3 server?

Discord

community	discord
-----------	---------

You'd rather use discord?

3.14.15 Video software

Just some additional software related to videos.

Viewing video

extra vlc

You might consider using vlc

Creating video

AUR obs-linuxbrowser-bin obs-glcapture-git obs-studio-git

obs-studio-git^{AUR} should be the right choice.

You can also make use of the plugins provided in the package list above.

Showing keystrokes

AUR	screenkey
-----	-----------

In order to show the viewers what keystrokes you're pressing, you can use something like ${\tt screenkey}^{\tt AUR}$

NOTE: For ideal use with obs, my dotfiles repository already provides you with the screenkey-obs alias for you to run with zsh.

Editing video

AUR davinci-resolve

In my case, I'm using davinci-resolve AUR .

Utilizing video

AUR tea	amviewer
---------	----------

Wanna remote control your own or another PC? $\texttt{teamviewer}^{\texttt{AUR}}$ might just be the right choice for you

3.14.16 Audio Production

You might have to edit /etc/security/limits.conf, to increase the allowed locked memory amount.

In my case I have 32GB of RAM and I want the audio group to be able to allocate most of the RAM, which is why I added the following line to the file

```
@audio - memlock 29360128
```

Ardour

To e.g. edit and produce audio, you could use ardour, because it's easy to use, stable and cross platform.

NOTE:

Ardour won't natively save in the mp3 format, due to licensing stuff. In order to create mp3 files, for sharing with other devices, because they have problems with wav files, for example, you can just use ffmpeg.

and after that we're going to convert in.wav to out.mp3

```
dustvoice@DustArch ~
$ ffmpeg -i in.wav -acodec mp3 out.mp3
```

Reaper

Instead of ardour, I'm using reaper, which is available for linux as a beta version, in my case more stable than ardour and more easy to use for me.

3.14.17 Virtualization

```
community virtualbox virtualbox-host-modules-arch
```

You might need to run another OS, for example Mac OS, from within Linux, e.g. for development/testing purposes. For that you can use virtualbox.

Now when you want to use virtualbox just load the kernel module

```
dustvoice@DustArch ~
$ sudo modprobe vboxdrv
```

and add the user which is supposed to run virtualbox to the vboxusers group

```
dustvoice@DustArch ~
pass:[$ sudo usermod -a G vboxusers $]USER
```

and if you want to use rawdisk functionality, also to the disk group

```
dustvoice@DustArch ~
pass:[$ sudo usermod -a G disk $]USER
```

Now just re-login and you're good to go.

3.14.18 Gaming

extra	pulseaudio pulseaudio-alsa	
community	lutris	
multilib	lib32-libpulse lib32-nvidia-utils steam	

The first option for native/emulated gaming on Linux is obviously steam.

The second option would be lutris, a program, that configures a wine instance correctly, etc.

3.14.19 Wacom

extra libwacom xf86-input-wacom

In order to use a Wacom graphics tablet, you'll have to install some packages You can now configure your tablet using the xsetwacom command.

3.14.20 VNC & RDP

extra	libvncserver
community	remmina
AUR	freerdp

In order to connect to a machine over VNC or to connect to a machine using the Remote Desktop Protocol, for example to connect to a Windows machine, I'll need to install freerdp^{AUR}, as well as libvncserver, for RDP and VNC functionality respectively, as well as remmina, to have a GUI client for those two protocols.

Now you can set up all your connections inside remmina.

Chapter 4

Upgrading the system

You're probably wondering why this gets a dedicated section.

You'll probably think that it would be just a matter of issuing

```
dustvoice@DustArch ~
$ sudo pacman -Syu
```

That's both true and false.

You have to make sure, that your boot partition is mounted at /boot in order for everything to upgrade correctly. That's because the moment you upgrade the linux package without having the correct partition mounted at /boot, your system won't boot. You also might have to do grub-mkconfig -o /boot/grub/grub.cfg after you install a different kernel image.

If your system **indeed doesn't boot** and **boots to a recovery console**, then double check that the issue really is the not perfectly executed kernel update by issuing

```
root@DustArch ~
$ uname -a
```

root@DustArch ~
\$ pacman -Q linux

The version of these two packages should be exactly the same! If it isn't there is an easy fix for it.

4.1 Fixing a faulty kernel upgrade

First off we need to restore the old linux package.

For that note the version number of

```
root@DustArch ~
$ uname -a
```

Now we'll make sure first that nothing is mounted at /boot, because the process will likely create some unwanted files. The process will also create a new /boot folder, which we're going to delete afterwards.

```
root@DustArch ~
$ umount /boot
```

Now cd into pacman's package cache

```
root@DustArch ~
$ cd /var/cache/pacman/pkg
```

There should be a file located named something like linux-<version>.pkg.tar.xz, where <version> would be somewhat equivalent to the previously noted version number

Now downgrade the linux package

```
root@DustArch ~
$ pacman -U linux-<version>.pkg.tar.xz
```

After that remove the possibly created /boot directory

```
root@DustArch ~
$ rm -rf /boot
root@DustArch ~
$ mkdir /boot
```

Now reboot and mount the boot partition, in my case an EFI $\,$ System $\,$ Partition. Now simply rerun

```
dustvoice@DustArch ~
$ sudo pacman -Syu
```

and you should be fine now.

Chapter 5

Additional notes

If you've printed this guide, you might want to add some additional blank pages for notes.
