## 1. Inside the archiso

This section is aimed at providing help with the general installation of a customized Arch Linux from within an official Arch Linux image (archiso).

As Arch Linux is a rolling release Linux distribution, it is advised, to have a working internet connection, in order to get the latest package upgrades and to install additional software, as the archiso only has very few packages available from cache.

a

Furthermore, one should bear in mind that depending on the version, or rather modification date, the guide may already be outdated. If you encounter any problems along the way, you will either have to resolve the issue yourself, or utilize the great ArchWiki, or the Arch Linux forums.

## 1.1. Syncing up pacman

First of all we need to sync up pacman's package repository, in order to be able to install packages

```
root@archiso ~ # pacman -Sy
```

Using pacman -Sy should be sufficient, in order to be able to search for packages from within the archiso, without upgrading the system, but might break your system, if you use this command on an existing installation!

To be on the safe side, it is advised to always use pacman -Syu instead!

pacstrap uses the latest packages anyways.

### 1.1.1. Official repositories

After doing that, we can now install any software from the official repositories by issuing

```
root@archiso ~ # pacman -S <package_name>
```

where you would replace <package\_name> with the actual package name.

If you don't know the exact package name, or if you just want to search for a keyword, for example xfce to list all packages having to do something with xfce, use

```
root@archiso ~ # pacman -Ss <keyword>
```

If you want to remove an installed package, just use

```
root@archiso ~ # pacman -Rsu <package_name>
```

If you have to force remove, which you should use **with extreme caution**, you can use

```
root@archiso ~ # pacman -Rdd <package_name>
```

#### **1.1.2.** AUR

If you want to install a package from the AUR, I would proceed as follows

1. cd into the dedicated directory, if you're using the dotfiles repo, which provides an update.sh script within that folder, to check every subfolder for updates

```
dustvoice@archiso ~ $ cd AUR
```

2. Clone the package with git

```
dustvoice@archiso ~/AUR $ git clone https://aur.archlinux.org/pacman-git.git
```

3. Switch to the package directory

```
dustvoice@archiso ~/AUR $ cd pacman-git
```

4. Execute makepkg

```
dustvoice@archiso ~/AUR/pacman-git $ makepkg -si
```

5. Delete all files created by makepkg, in order to easily see, if a package needs an update by using git fetch --all and git status

```
dustvoice@archiso ~/AUR/pacman-git $ git reset HEAD --hard dustvoice@archiso ~/AUR/pacman-git $ git clean -fdx
```

You might have to resolve any AUR dependencies, which can't be resolved with pacman.

In order to install that AUR package, you **must** switch to your normal user, because makepkg doesn't run as root.

### 1.1.3. Software categories

In this guide, I'll be marking some headings according to which kind of software it uses.

There are three categories of software:

- Console software is intended to be used with either the native linux console, or with a terminal emulator
- GUI software is intended to be used in a graphical desktop environment
- Hybrid software can either be used within both a console and a graphical desktop environment (networkmanager), or there are packages available for both console and a graphical desktop environment (pulseaudio with pulsemixer for console and pavucontrol for GUI

### 1.1.4. Software installation

In this guide, I'll be explicitly mark the packages installed in a specific section.

This enables you to

- clearly see what packages get installed / need to be installed in a specific section
- install packages before you start with the section in order to minimize waiting time
- not have to read through bloating lines like

```
dustvoice@DustArch ~
$ sudo pacman -S some-package
```

• not have to accidentally reinstall already installed packages

The packages are always the recommended packages.

For further clarification for specific packages (e.g. UEFI specific packages), continue reading the section, as there is most certainly a explanation there.

Of course, you can adapt everything to your needs, especially in the [additional-setup-packages] step.

### 1.1.4.1. Example section

Software	Packages
core	libutil-linux
extra	git
community	ardour cadence jsampler linuxsampler qsampler sample-package
AUR	sbupdate

You have to configure sample-package by editing /etc/sample.conf

/etc/sample.conf

Sample.text=useful

### 1.2. Formatting the drive

First you have to list all the available drives by issuing

```
root@archiso ~ # fdisk -l
```

The output of fdisk -l is dependent on your system configuration.

In my case, the partition I want to install the root file system on is /dev/sdb2. /dev/sdb3 will be my swap partition.

A swap size **twice the size of your RAM** is recommended by a lot of people.

With bigger RAM sizes available today, this isn't necessary anymore. To be exact, every distribution has different recommendations for swap sizes.

Also swap size heavily depends on whether you want to be able to hibernate, etc.

You should make the swap size at least your RAM size and for RAM sizes over 4GB and the wish to hibernate, at least one and a half your RAM size.

If you haven't yet partitioned your disk, please refer to the general partitioning tutorial in the ArchWiki.

Now we need to format the partitions accordingly

```
root@archiso ~ # mkfs.ext4 /dev/sdb2
root@archiso ~ # mkswap /dev/sdb3
```

After doing that, we can turn on the swap and mount the root partition.

```
root@archiso ~ # swapon /dev/sdb3
root@archiso ~ # mount /dev/sdb2 /mnt
```

If you have an additional EFI system partition, because of a *UEFI - GPT* setup or e.g. an existing Windows installation, which we will assume to be located under /dev/sda2 (/dev/sda is the disk of my Windows install), you'll have to mount this partition to the new systems /boot folder

```
root@archiso ~ # mkdir /mnt/boot
root@archiso ~ # mount /dev/sda2 /mnt/boot
```

## 1.3. Preparing the chroot environment

First it might make sense to edit /etc/pacman.d/mirrorlist to move the mirror(s) geographically closest to you to the top.

After that we can pacstrap the **minimum packages** needed. We will install all other packages later on.

This is the actual command used in my case

root@archiso ~ # pacstrap /mnt base linux linux-firmware

After that generate an fstab using genfstab

```
root@archiso ~ # genfstab -U /mnt >> /mnt/etc/fstab
```

and you're ready to enter the chroot environment.

# 2. Entering the chroot

As we want to set up our new system, we need to have access to the different partitions, the internet, etc. which we wouldn't get by solely using chroot.

That's why we are using arch-chroot, provided by the arch-install-scripts package already shipped with the archiso. This script takes care of all that stuff, so we can set up our system properly.

root@archiso ~ # arch-chroot /mnt

Et Voila! You successfully chrooted inside your new system and you'll be greeted by a bash prompt.

## 2.1. Installing additional packages

Softw	vare Packages
core	amd-ucode base-devel diffutils dmraid dnsmasq dosfstools efibootmgr exfat-utils grub iputils lvm2 openssh sudo usbutils
extra	efitools git intel-ucode networkmanager networkmanager-openconnect networkmanager- openvpn parted polkit rsync zsh
community	neovim os-prober

There are many command line text editors available, like nano, vi, vim, emacs, etc.

I'll be using neovim, though it shouldn't matter what editor you choose.

Make sure to enable the NetworkManager.service service, in order for the Internet connection to work upon booting into our fresh system later on.

```
[root@archiso /]# systemctl enable NetworkManager.service
```

With polkit installed, create a file /etc/polkit-1/rules.de/50-org.freedesktop.NetworkManager.rules to enable users of the network group to add new networks without the need of sudo.

/etc/polkit-1/rules.de/50-org.freedesktop.NetworkManager.rules

```
polkit.addRule(function(action, subject) {
    if (action.id.indexOf("org.freedesktop.NetworkManager.") == 0 &&
    subject.isInGroup("network")) {
        return polkit.Result.YES;
    }
});
```

If you use UEFI, you'll also need the efibootmgr in order to modify the UEFI entries.

### 2.2. Master of time

After that you have to set your timezone and update the system clock.

Generally speaking, you can find all the different timezones under /usr/share/zoneinfo. In my case, my timezone resides under /usr/share/zoneinfo/Europe/Berlin.

To achieve the desired result, I want to symlink this to /etc/localtime and set the hardware clock.

```
[root@archiso /]# ln -s /usr/share/zoneinfo/Europe/Berlin /etc/localtime
[root@archiso /]# hwclock --systohc --utc
```

Now you can also enable time synchronization over network

```
[root@archiso /]# timedatectl set-timezone Europe/Berlin
[root@archiso /]# timedatectl set-ntp true
[root@archiso /]# timedatectl status
```

and check that everything is alright

```
[root@archiso /]# timedatectl status
```

### 2.3. Master of locales

Now you have to generate your locale information.

For that you have to edit /etc/locale.gen and uncomment the locales you want to enable.

I recommend to always uncomment en\_US.UTF-8 UTF8, even if you want to use another language primarily.

In my case I only uncommented the en\_US.UTF-8 UTF8 line

/etc/locale.gen

```
en_US.UTF-8 UTF8
```

After that you still have to actually generate the locales by issuing

```
[root@archiso /]# locale-gen
```

and set the locale

```
[root@archiso /]# localectl set-locale LANG="en_US.UTF-8"
```

After that we're done with this part.

# 2.4. Naming your machine

2.4. Naming your machine
Now we can set the hostname and add hosts entries.
Apart from being mentioned in your command prompt, the hostname also serves the purpose of identifying, or naming your machine. This enables you to see your PC in your router, etc.

#### **2.4.1.** hostname

tc/hostname			
DustArch			

### **2.4.2.** hosts

Now we need to specify some hosts entries by editing /etc/hosts

#### /etc/hosts

```
# Static table lookup for hostnames.
# See hosts(5) for details.

127.0.0.1 localhost .
::1 localhost .
127.0.1.1 DustArch.localhost DustArch
```

# 2.5. User setup

1
Now you should probably change the default root password and create a new non-root user for yourself, as using your new system purely through the native root user is not recommended from a security standpoint.

# 2.5.1. Give root a password

[root@archiso /]# passwd

and choose a new password.

### 2.5.2. Create a personal user

Software	Packages
core	sudo
extra	zsh

We are going to create a new user and set the password, groups and shell for this user

```
[root@archiso /]# useradd -m -p "" -G
"adm,audio,disk,floppy,kvm,log,lp,network,rfkill,scanner,storage,users,optical,power,w
heel" -s /usr/bin/zsh dustvoice
[root@archiso /]# passwd dustvoice
```

We now have to allow the wheel group sudo access.

For that we edit /etc/sudoers and uncomment the <code>%wheel</code> line

/etc/sudoers

```
%wheel ALL=(ALL) ALL
```

You could also add a new line below the root line

/etc/sudoers

```
root ALL=(ALL) ALL
```

with your new username

/etc/sudoers

```
dustvoice ALL=(ALL) ALL
```

to solely grant the new user sudo privileges.

# **2.6.** grub

Software	Packages
core	efibootmgr grub

Now onto installing the boot manager. We will use grub in this guide.

First make sure, all the required packages are installed

```
[root@archiso /]# pacman -S grub dosfstools os-prober mtools
```

and if you want to use **UEFI**, also

```
[root@archiso /]# pacman -S efibootmgr
```

### **2.6.1.** BIOS

If you chose the <code>BIOS - MBR</code> variation, you'll have to **do nothing special** 

If you chose the BIOS - GPT variation, you'll have to **have a +1M boot partition** created with the partition type set to BIOS boot.

In both cases you'll have to run the following comman now

[root@archiso /]# grub-install --target=i386-pc /dev/sdb

It should obvious that you would need to replace /dev/sdb with the disk you actually want to use. Note however that you have to specify a disk and not a partition, so no number.

#### 2.6.2. UEFI

If you chose the UEFI - GPT variation, you'll have to **have the EFI System Partition mounted** at /boot (where /dev/sda2 is the partition holding said EFI System Partition in my particular setup)

Now install grub to the EFI System Partition

```
[root@archiso /]# grub-install --target=x86_64-efi --efi-directory=/boot --bootloader
-id=grub --recheck
```

If you've planned on dual booting arch with Windows and therefore reused the EFI System Partition created by Windows, you might not be able to boot to grub just yet.

In this case, boot into Windows, open a cmd window as Administrator and type in

```
bcdedit /set {bootmgr} path \EFI\grub\grubx64.efi
```

To make sure that the path is correct, you can use

```
[root@archiso /]# ls /boot/EFI/grub
```

under Linux to make sure, that the <code>grubx64.efi</code> file is really there.

# 262 acub confi

2.6.3. grub config
In all cases, you now have to create the main grub.cfg configuration file.
But before we actually generate it, we'll make some changes to the default <code>grub</code> settings, which the <code>grub.cfg</code> will be generated from.

#### 2.6.3.1. Adjust the timeout

First of all, I want my grub menu to wait indefinitely for my command to boot an OS.

/etc/default/grub

GRUB\_TIMEOUT=-1

I decided on this, because I'm dual booting with Windows and after Windows updates itself, I don't want to accidentally boot into my Arch Linux, just because I wasn't quick enough to select the Windows Boot Loader from the grub menu.

Of course you can set this parameter to whatever you want.

Another way of achieving what I described, would be to make grub remember the last selection.

/etc/default/grub

GRUB\_TIMEOUT=5
GRUB\_DEFAULT=saved
GRUB\_SAVEDEFAULT="true"

### 2.6.3.2. Enable the recovery

/etc/default/grub

GRUB\_DISABLE\_RECOVERY=false

#### 2.6.3.3. NVIDIA fix

Now, as I'm using the binary NVIDIA driver for my graphics card, I also want to make sure, to revert <code>grub</code> back to text mode, after I select a boot entry, in order for the NVIDIA driver to work properly. You might not need this

/etc/default/grub

GRUB\_GFXPAYLOAD\_LINUX=text

### 2.6.3.4. Add power options

I also want to add two new menu entries, to enable me to shut down the PC, or reboot it, right from the grub menu.

/etc/grub.d/40-custom

```
menuentry '=> Shutdown' {
    halt
}
menuentry '=> Reboot' {
    reboot
}
```

### 2.6.3.5. Installing memtest

0
As I want all possible options to possibly troubleshoot my PC right there in my <code>grub</code> menu, withou the need to boot into a live OS, I also want to have a memory tester there.

#### **2.6.3.5.1.** BIOS

Software Packages		
extra	memtest86+	

For a BIOS setup, you'll simply need to install the memtest86+ package, with no further configuration.

Software Packages		
AUR	memtest86-efi	

For a  ${\sf UEFI}$  setup, you'll first need to install the package and then tell  ${\sf memtest86-efi}^{\sf AUR}$  how to install itself

[root@archiso /]# memtest86-efi -i

Now select option 3, to install it as a grub2 menu item.

#### 2.6.3.6. Enabling hibernation

In order to use the hibernation feature, you'll have to make sure that your swap partition/file is at least the size of your RAM.

After that we need to perform two tasks

1. Add the resume hook to /etc/mkinitcpio.conf, before fsck and definetely after block

/etc/mkinitcpio.conf

HOOKS=(base udev autodetect modconf block filesystems keyboard resume fsck)

2. Add the resume kernel parameter to /etc/default/grub, containing my swap partition UUID, in my case

/etc/default/grub

GRUB\_CMDLINE\_LINUX\_DEFAULT="loglevel=3 quiet resume=UUID=097c6f11-f246-40eb-a702-ba83c92654f2"

After that we have to run

[root@archiso /]# mkinitcpio -p linux

If you have to change anything, like the swap partition UUID, inside the grub configuration files, you'll always have to rerun grub-mkconfig as explained in Generating the grub config.

#### 2.6.3.7. Generating the grub config

Now we can finally generate our grub.cfg

[root@archiso /]# grub-mkconfig -o /boot/grub/grub.cfg

Now you're good to boot into your new system.

2.7. Secure Boot		

#### 2.7.1. shim

This is a way of handling secure boot that aims at just making everything work!

It is not the way Secure Boot was intended to be used and you might as well disable it.

If you need Secure Boot to be enabled, e.g. for Windows, but you couldn't care less for the security it could bring to your device, use this method.

If you want to actually make use of the Secure Boot feature, read The manual way.

Software	Packages
AUR	shim-signed

I know I told you that you're now good to boot into your new system. That is only correct, if you're **not** using Secure Boot.

You can either proceed by disabling Secure Boot in your firmware settings, or by using shim as kind of a pre-bootloader, as well as signing your bootloader (grub) and your kernel.

If you decided on using Secure Boot, you will first have to install the package.

Now we just need to copy shimx64.efi, as well as mmx64.efi to our EFI System Partition

```
[root@archiso /]# cp /usr/share/shim-signed/shimx64.efi /boot/EFI/grub/
[root@archiso /]# cp /usr/share/shim-signed/mmx64.efi /boot/EFI/grub/
```

a

If you have to use bcdedit from within Windows, as explained previously, you need to adapt the command accordingly

bcdedit /set {bootmgr} path \EFI\grub\shimx64.efi

Now you will be greeted by MokManager everytime you update your bootloader or kernel.

Just choose Enroll hash from disk and enroll your bootloader (grubx64.efi) and kernel (vmlinuz-linux).

Reboot and your system should fire up just fine.

2.7.2. The manual way		

## 3. Inside the DustArch

This section helps at setting up the customized system from within an installed system.

This section mainly provides aid with the basic set up tasks, like networking, dotfiles, etc.

Not everything in this section is mandatory.

A

This section is rather a guideline, because it is easy to forget some steps needed, for example jack for audio production, that only become apparent, when they're needed.

It is furthermore the responsibility of the reader to decide which steps to skip and which need further research. As I mentioned, this is only a guide and not the answer to everything.

### 3.1. Someone there?

First we have to check if the network interfaces are set up properly.

To view the network interfaces with all their properties, we can issue

DustArch% ip link

To make sure that you have a working Internet connection, issue

DustArch% ping archlinux.org

Everything should run smoothly if you have a wired connection.

If there is no connection and you're indeed using a wired connection, try restarting the NetworkManager service

DustArch% sudo systemctl restart NetworkManager.service

and then try pinging again.

If you're trying to utilize a Wi-Fi connection, use nmcli, the NetworkManager's command line tool, or nmtui, the NetworkManager terminal user interface, to connect to a Wi-Fi network.

I never got nmtui to behave like I wanted it to, in my particular case at least, which is the reason why I use nmcli or the GUI tools.

First make sure, the scanning of nearby Wi-Fi networks is enabled for your Wi-Fi device

DustArch% nmcli radio

and if not, enable it

DustArch% nmcli radio wifi on

Now make sure your Wi-Fi interface appears under

DustArch% nmcli device

Rescan for available networks

DustArch% nmcli device wifi rescan

and list all found networks

DustArch% nmcli device wifi list

After that connect to the network

DustArch% nmcli device wifi connect --ask

Now try pinging again.

# 3.2. Update and upgrade

After making sure that you have a working Internet connection, you can then proceed to update

and upgrade all installed packages by issuing	-	_	
DustArch% sudo pacman -Syu			

# 3.3. Enabling the multilib repository

In order to make 32-bit packages available to pacman, we'll need to enable the multilib repository in /etc/pacman.conf first. Simply uncomment

/etc/pacman.conf

```
[multilib]
Include = /etc/pacman.d/mirrorlist
```

and update pacman's package repositories afterwards

DustArch% sudo pacman -Syu

## 3.4. zsh for president

Of course you can use any shell you want. In my case I'll be using the zsh shell.

I am using zsh because of its auto completion functionality and extensibility, as well as a brilliant vim like navigation implementation through a plugin, though that might not be what you're looking for.

We already set the correct shell for the dustvoice user in the Create a personal user step, but I want to use zsh for the root user too, so I'll have to change root's default shell to it.

DustArch% sudo chsh -s /usr/bin/zsh root

Don't worry about the looks by the way, we're gonna change all that in just a second.

# 3.5. git

Software	Packages
extra	git

Install the package and you're good to go for now, as we'll care about the <code>.gitconfig</code> in just a second.

# 3.6. Security is important

Software	Packages
core	gnupg

If you've followed the tutorial using a recent version of the archiso, you'll probably already have the most recent version of gnupg installed by default.

### 3.6.1. Smartcard shenanigans

Software Packages		
extra	libusb-compat	
community	ccid opensc pcsclite	

DustArch% sudo pacman -S pcsclite libusb-compat ccid opensc

After that you'll still have to setup gnupg correctly. In my case I have my private keys stored on a smartcard.

To use it, I'll have to install the listed packages and then enable and start the pcscd service

DustArch% sudo systemctl enable pcscd.service DustArch% sudo systemctl start pcscd.service

After that, you should be able to see your smartcard being detected

DustArch% gpg --card-status

If your smartcard still isn't detected, try logging off completely or even restarting, as that sometimes is the solution to the problem.

# 3.7. Additional required tools

Software Packages	
core	make openssh
extra	clang cmake jdk-openjdk python
community	pass

To minimize the effort required by the following steps, we'll install most of the required packages beforehand

This will ensure, we proceed through the following section without the need for interruption, because a package needs to be installed, so the following content can be condensed to the relevant informations.

### 3.8. Setting up a home environment

In this step we're going to setup a home environment for both the root and my personal dustvoice user.

In my case these 2 home environments are mostly equivalent, which is why I'll execute the following commands as the dustvoice user first and then switch to the root user and repeat the same commands.

I decided on this, as I want to edit files with elevated permissions and still have the same editor style and functions/plugins.

a

Note that this comes with some drawbacks. For example, if I change a configuration for my dustvoice user, I would have to regularly update it for the root user too. This bears the problem, that I have to register my smartcard for the root user. This in turn is problematic, cause the gpg-agent used for ssh authentication, doesn't behave well when used within a su or sudo -i session. So in order to update root's config files I would either need to symlink everything, which I won't do, or I'll need to login as the root user now and then, to update everything.

In my case, I want to access all my git repositories with my gpg key on my smartcard. For that I have to configure the gpg-agent with some configuration files that reside in a git repository. This means I will have to reside to using the https URL of the repository first and later changing the URL either in the corresponding .git/config file, or by issuing the appropriate command.

#### 3.8.1. Use dotfiles for a base config

To provide myself with a base configuration, which I can then extend, I have created a dotfiles repository, which contains all kinds of configurations.

The special thing about this dotfiles repository is that it is my home folder. By using a curated .gitignore file, I'm able to only include the configuration files I want to keep between installs into the repository and ignore everything else.

To achieve this very specific setup, I have to turn my home directory into said dotfiles repository first

```
DustArch% git init
DustArch% git remote add origin https://github.com/DustVoice/dotfiles.git
DustArch% git fetch
DustArch% git reset origin/master --hard
DustArch% git branch --set-upstream-to=origin/master master
```

Now I can issue any git command in my ~ directory, because it now is a git repository.

#### 3.8.2. Set up gpg

As I wanted to keep my dotfiles repository as modular as possible, I utilize git's submodule feature. Furthermore I want to use my nvim repository, which contains all my configurations and plugins for neovim, on Windows, but without all the Linux specific configuration files. I am also using the Pass repository on my Android phone and Windows PC, where I only need this repository without the other Linux configuration files.

Before we'll be able to update the submodules (nvim config files and password-store) though, we will have to setup our gpg key as an ssh key, as I use it to authenticate

```
dustvoice@DustArch ~

$ chmod 700 .gnupg
dustvoice@DustArch ~

$ gpg --card-status
dustvoice@DustArch ~

$ gpg --card-edit
```

```
(insert) gpg/card> fetch
(insert) gpg/card> q
```

```
dustvoice@DustArch ~
$ gpg-connect-agent updatestartuptty /bye
```

You would have to adapt the keygrip present in the ~/.gnupg/sshcontrol file to your specific keygrip, retrieved with gpg -K --with-keygrip.

Now, as mentioned before, I'll switch to using ssh for authentication, rather than https

```
dustvoice@DustArch ~
$ git remote set-url origin git@github.com:DustVoice/dotfiles.git
```

As the best method to both make zsh recognize all the configuration changes, as well as the gpgagent behave properly, is to re-login, we'll do just that

```
dustvoice@DustArch ~
$ exit
```

It is very important to note, that I mean a real re-login.

That means that if you've used ssh to log into your machine, it probably won't be sufficient to login into a new ssh session. You'll probably need to restart the machine completely.

#### 3.8.3. Finalize the dotfiles

Now log back in and continue

```
dustvoice@DustArch ~
$ git submodule update --init --recursive
dustvoice@DustArch ~
$ source .zshrc
dustvoice@DustArch ~
$ cd .config/nvim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:platform = "linux"' >> platform.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_autocomplete = 3' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_clang_format = 1' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ echo 'let g:use_font = 0' >> custom.vim
dustvoice@DustArch ~/.config/nvim
$ sudo pip3 install neovim
dustvoice@DustArch ~/.config/nvim
$ nvim --headless +PlugInstall +ga
dustvoice@DustArch ~/.config/nvim
$ cd plugged/YouCompleteMe
dustvoice@DustArch ~/.config/nvim/plugged/YouCompleteMe
$ python3 install.py --clang-completer --java-completer
dustvoice@DustArch ~/.config/nvim/plugged/YouCompleteMe
$ cd ~
```

#### 3.8.4. gpg-agent forwarding

Now there is only one thing left to do, in order to make the gpg setup complete: gpg-agent forwarding over ssh. This is very important for me, as I want to use my smartcard on my development server too, which requires me, to forward/tunnel my gpg-agent to my remote machine.

First of all, I want to setup a config file for ssh, as I don't want to pass all parameters manually to ssh every time.

~/.ssh/config

```
Host <connection name>
    HostName <remote address>
    ForwardAgent yes
    ForwardX11 yes
    RemoteForward <remote agent-socket> <local agent-extra-socket>
    RemoteForward <remote agent-ssh-socket> <local agent-ssh-socket>
```

You would of course, need to adapt the content in between the < and > brackets.

```
dustvoice@DustArch ~
$ !gpgconf --list-dirs
```

Now you'll still need to enable some settings on the remote machine(s).

/etc/ssh/sshd\_config

StreamLocalBindUnlink yes AllowAgentForwarding yes X11Forwarding yes

Now just restart your remote machine(s) and you're ready to go.

### 3.8.5. Back to your roots

As mentioned before, you would now switch to the root user, either by logging in as root, or by using

```
dustvoice@DustArch ~
$ sudo -iu root
```

Now go back to Setting up a home environment to repeat all commands for the root user.

A native login would be better compared to sudo -iu root, as there could be some complications, like already running gpg-agent instances, etc., which you would need to manually resolve, when using sudo -iu root.

### 3.9. fstab

In my case, I'm sharing an exFat partition between my DustArch and my Windows. This was a result of some major inconvenience because of some weird NTFS permission stuff, which apparently Windows didn't like. Since I've avoided directly writing to Windows partitions since then, I'll quickly demonstrate what fstab entries I have and why

#### /etc/fstab

```
1 UUID=e26de048-6147-42e5-a34b-59f1a50621bb
                                                     /
                                                                      ext4
  rw, relatime
                           0 1
2
3 UUID="C8E3-A0FD"
                                                     /boot
                                                                      vfat
                           0 1
 defaults
4
5 UUID="DC88-5A4E"
                                                     /mnt/projects
                                                                      exfat
  rw,relatime
                           0 0
6
7 UUID=7A16569B51903310
                                                     /mnt/data
                                                                      ntfs
  ro, nosuid, nodev, noauto 00
```

#### The

- 1. entry should be pretty straight forward. It's my root partition of my DustArch install.
- 2. entry is quite important too. It's my EFI System Partition, which gets mounted at boot time, in order to prevent kernel orphaning, which means, that the kernel version installed on the system doesn't match the one on the boot partition.
- 3. entry is my shared exFat partition, which we are allowed to write to.
- 4. entry is important, because of the options. These options prevent me from modifying files on that NTFS partition.

#### \_ 4 0 **T** •

Well, why wouldn't you want audio	•••		
wen, willy wouldn't you want addit	•••		

#### 3.10.1. alsa

Software	Packages
extra	alsa-utils

You're probably better off using pulseaudio and/or jack.

Now choose the sound card you want to use

dustvoice@DustArch ~
\$ cat /proc/asound/cards

and then create /etc/asound.conf

/etc/asound.conf

defaults.pcm.card 2
defaults.ctl.card 2

It should be apparent, that you would have to switch out 2 with the number corresponding to the sound card you want to use.

#### 3.10.2. pulseaudio

Software Packages		
extra	pavucontrol pulseaudio	
community	pulsemixer	

Some applications require pulseaudio, or work better with it, for example discord, so it might make sense to use pulseaudio

For enabling real-time priority for pulseaudio on Arch Linux, please make sure your user is part of the audio group and edit the file /etc/pulse/daemon.conf, so that you uncomment the lines

/etc/pulse/daemon.conf

```
high-priority = yes
nice-level = -11

realtime-scheduling = yes
realtime-priority = 5
```

If your system can handle the load, you can also increase the remixing quality, by changing the resample-method

/etc/pulse/daemon.conf

```
resample-method = speex-float-10
```

Of course a restart of the pulseaudio daemon is necessary to reflect the changes you just made

```
dustvoice@DustArch ~

$ pulseaudio --kill
dustvoice@DustArch ~

$ pulseaudio --start
```

### **3.10.3.** jack

Software Packages		
extra	pulseaudio-jack	
community	cadence jack2	

If you either want to manually control audio routing, or if you use some kind of audio application like ardour, you'll probably want to use jack and cadence as a GUI to control it, as it has native support for bridging pulseaudio to jack.

## 3.10.4. Audio handling

Software Packages	
extra	libao libid3tag libmad libpulse opus wavpack
community	sox twolame

To also play audio, we need to install the mentioned packages and then simply do

```
dustvoice@DustArch ~

$ play audio.wav
dustvoice@DustArch ~

$ play audio.mp3
```

to play audio.

### 3.11. Bluetooth

Software Packages	
extra	bluez bluez-util pulseaudio-bluetooth
community	blueman

To set up Bluetooth, we need to install the bluez and bluez-utils packages in order to have at least a command line utility bluetoothctl to configure connections

Now we need to check if the btusb kernel module was already loaded

```
dustvoice@DustArch ~
$ sudo lsmod | grep btusb
```

After that we can enable and start the bluetooth, service service

```
dustvoice@DustArch ~

$ sudo systemctl enable bluetooth.service
dustvoice@DustArch ~

$ sudo systemctl start bluetooth.service
```

To use bluetoothctl and get access to the Bluetooth device of your PC, your user needs to be a member of the lp group.

Now simply enter bluetoothctl

```
dustvoice@DustArch ~
$ bluetoothctl
```

In most cases your Bluetooth interface will be preselected and defaulted, but in some cases, you might need to first select the Bluetooth controller

```
(insert) [DustVoice]# list
(insert) [DustVoice]# select <MAC_address>
```

After that, power on the controller

```
(insert) [DustVoice]# power on
```

Now enter device discovery mode

```
(insert) [DustVoice]# scan on
```

```
(insert) [DustVoice]# devices
```

You can turn device discovery mode off again, after your desired device has been found

(insert) [DustVoice]# scan off

Now turn on the agent

```
(insert) [DustVoice]# agent on
```

and pair with your device

```
(insert) [DustVoice]# pair <MAC_address>
```

If your device doesn't support PIN verification you might need to manually trust the device

(insert) [DustVoice]# trust <MAC\_address>

Finally connect to your device

(insert) [DustVoice]# connect <MAC\_address>

If your device is an audio device, of some kind you might have to install pulseaudio-bluetooth and append 2 lines to /etc/pulse/system.pa as well.

append the following 2 lines

/etc/pulse/system.pa

```
load-module module-bluetooth-policy
load-module module-bluetooth-discover
```

and restart pulseaudio

```
dustvoice@DustArch ~

$ pulseaudo --kill
dustvoice@DustArch ~

$ pulseaudo --start
```

If you want a GUI to do all of this, just install blueman and launch blueman-manager

# 3.12. Graphical desktop environment

Software Packages	
extra	ttf-hack xorg xorg-drivers xorg-xinit
community	arandr alacritty i3 i3status rofi

If you decide, that you want to use a graphical desktop environment, you have to install additional packages in order for that to work.

dustvoice@DustArch ~
\$ sudo pacman -S xorg xorg-xinit xorg-drivers i3 i3status rofi ttf-hack xfce4-terminal arandr

#### 3.12.1. NVIDIA

Software Packages	
extra	nvidia nvidia-utils nvidia-settings opencl- nvidia

If you also want to utilize special NVIDIA functionality, for example for davinci-resolve, you'll most likely need to install their proprietary driver

You would have to reboot sooner or later after installing the NVIDIA drivers.

Also to get the best performance, at least for something like screen capturing in obs, go to X Server Display Configuration inside nvidia-settings, switch to Advanced and enable Force Composition Pipeline, as well as Force Full Composition Pipeline.

	3.12.2. Launching the graphical environment	
After that you can now do startx in order to launch the graphical environment.		
	If anything goes wrong in the process, remember that you can press <b>Ctrl+Alt+<number></number></b> to switch ttys.	

#### **3.12.2.1. The NVIDIA way**

Software Packages	
community	bbswitch
AUR	nvidia-xrun

If you're using an NVIDIA graphics card, you might want to use nvidia-xrun<sup>AUR</sup> instead of startx. This has the advantage, of the nvidia kernel modules, as well as the nouveau ones not loaded at boot time, thus saving power. nvidia-xrun<sup>AUR</sup> will then load the correct kernel modules and run the .nvidia-xinitrc script in your home directory (for more file locations look into the documentation for nvidia-xrun<sup>AUR</sup>).

At the time of writing, nvidia-xrun<sup>AUR</sup> needs sudo permissions before executing its task.

Software	Packages
AUR	nvidia-xrun-pm

If your hardware doesn't support bbswitch, you would need to use nvidia-xrun-pm<sup>AUR</sup> instead.

Now we need to blacklist **both nouveau and nyidia** kernel modules.

To do that, we first have to find out, where our active modprobe.d directory is located. There are 2 possible locations, generally speaking: /etc/modprobe.d and /usr/lib/modprobe.d. In my case it was the latter, which I could tell, because this directory already had files in it.

Now I'll create a new file named nvidia-xrun.conf and write the following into it

/usr/lib/modprobe.d/nvidia-xrun.conf

- 1 blacklist nvidia
- 2 blacklist nvidia-drm
- 3 blacklist nvidia-modeset
- 4 blacklist nvidia-uvm
- 5 blacklist nouveau

With this config in place,

```
dustvoice@DustArch ~
$ lsmod | grep nvidia
```

and

```
dustvoice@DustArch ~
$ lsmod | grep nouveau
```

should return no output. Else you might have to place some additional entries into the file.

If you installed nvidia-xrun-pm instead of nvidia-xrun and bbswitch, you might want to also enable the nvidia-xrun-pm service

```
dustvoice@dustArch ~
$ sudo systemctl enable nvidia-xrun-pm.service
```

The required .nvidia-xinitrc file, mentioned previously, should already be provided in the dotfiles repository.

Now instead of startx, just run nvidia-xrun, enter your sudo password and you're good to go.

# 3.13. Additional console software

oftware that is useful in combination with a console.	

### **3.13.1.** tmux

Software Packages	
community	tmux

I would reccommend to install tmux which enables you to have multiple terminal instances (called windows in tmux) open at the same time. This makes working with the linux terminal much easier.

To view a list of keybinds, you just need to press CTRL+b followed by ?.

### 3.13.2. Communication

3.13.2. Communication
Life is all about communicating. Here are some pieces of software to do exactly that.

Software Packages		
community	weechat	

weechat is an IRC client for the terminal, with the best features and even a vim mode, by using a plugin

To configure everything, open weechat

```
dustvoice@DustArch ~
$ weechat
```

and install vimode, as well as configure it

```
/script install vimode.py
/vimode bind_keys
/set plugins.var.python.vimode.mode_indicator_normal_color_bg "blue"
```

Now add mode\_indicator+ in front of and ,[vi\_buffer] to the end of weechat.bar.input.items, in my case

```
/set weechat.bar.input.items
"mode_indicator+[input_prompt]+(away),[input_search],[input_paste],input_text,[vi_buff
er]
```

Now add ,cmd\_completion to the end of weechat.bar.status.items, in my case

```
/set weechat.bar.status.items
"[time],[buffer_last_number],[buffer_plugin],buffer_number+:+buffer_name+(buffer_modes
)+{buffer_nicklist_count}+buffer_zoom+buffer_filter,scroll,[lag],[hotlist],completion,
cmd_completion"
```

Now enable vimode searching

```
/set plugins.var.python.vimode.search_vim on
```

Now you just need to add a new connection, for example irc.freenode.net

```
/server add freenode irc.freenode.net
```

and connect to it

#### /connect freenode

You might need to authenticate with NickServ, before being able to write in a channel

/msg NickServ identify <password>

Instead of directly /setting the values specified above, you can also do

/fset weechat.var.name

select the entry you want to modify (for example for plugins.var.python.vimode) and then press s (make sure you're in insert mode) and Return, in order to modify the existing value.

#### **3.13.3. PDF viewer**

Software Packages		
extra	ghostscript	
community	fbida	

To use asciidoctor-pdf, you might be wondering how you are supposed to open the generated PDFs from the native linux console.

This fbida package provides the fbgs software, which renders a PDF document using the native framebuffer.

To view this PDF document (Documentation.pdf) for example, you would run

dustvoice@DustArch ~
\$ fbgs Documentation.pdf

You can view all the controls by pressing h.

# 3.14. Additional hybrid software

Some additional software providing some console only environment nevertheless.	kind	of GUI	to v	work	with,	but	that	can	be	useful	in a

### 3.14.1. Password management

5.11.1. 1055WOTU MUMUGEMENT
I'm using pass as my password manager. As we already installed it in the Additional required tool step and updated the submodule that holds our .password-store, there is nothing left to do in this step.

## **3.14.2.** python

Software Packages		
extra	python	

Python has become really important for a magnitude of use cases.

### 3.14.3. ruby & asciidoctor

Software Packages		
extra	ruby rubygems	

In order to use asciidoctor, we have to install ruby and rubygems. After that we can install asciidoctor and all its required gems.

If you want to have pretty and highlighted source code, you'll need to install a code formatter too.

For me there are mainly two options

• pygments.rb, which requires python to be installed

```
dustvoice@DustArch ~
$ gem install pygments.rb
```

• rouge which is a native ruby gem

```
dustvoice@DustArch ~
$ gem install rouge
```

Now the only thing left, in my case at least, is adding  $\sim$ /.gem/ruby/2.7.0/bin to your path.

Please note that if you run a ruby version different from 2.7.0, or if you upgrade your ruby version, you have to use the bin path for that version.

For zsh you'll want to add a new entry inside the .zshpath file

~/.zshpath

```
path+=("$HOME/.gem/ruby/2.7.0/bin")
```

which then gets sourced by the provided .zshenv file. An example is provided with the .zshpath.example file

You might have to re-source the .zshenv file to make the changes take effect immediately

```
dustvoice@DustArch ~
$ source .zshenv
```

If you want to add a new entry to the path variable, you have to append it to the array

~/.zshpath

path=("\$HOME/.gem/ruby/2.7.0/bin" "\$HOME/.gem/ruby/2.6.0/bin")

If you use another shell than zsh, you might have to do something different, to add a directory to your PATH.

### 3.14.4. JUCE and FRUT

JUCE is a header only library for C++ that enables you to develop cross-platform applications with a single codebase.

FRUT makes it possible to manage JUCE projects purely from cmake.

```
dustvoice@DustArch ~

$ git clone https://github.com/WeAreROLI/JUCE.git
dustvoice@DustArch ~

$ cd JUCE
dustvoice@DustArch ~/JUCE

$ git checkout develop
dustvoice@DustArch ~/JUCE

$ cd ..
dustvoice@DustArch ~

$ git clone https://github.com/McMartin/FRUT.git
```

### **3.14.4.1. Using JUCE**

Software Packages				
core gcc gnutls				
extra	alsa-lib clang freeglut freetype2 ladspa libx11 libxcomposite libxinerama libxrandr mesa webkit2gtk			
community	jack2 libcurl-gnutls			
multilib	lib32-freeglut			

In order to use JUCE, you'll need to have some dependency packages installed, where ladspa and lib32-freeglut are not neccessarily needed.

### 3.14.5. Additional development tools

Here are just some examples of development tools one could install in addition to what we already have.

### 3.14.5.1. Code formatting

Software Packages	
community	astyle

We already have clang-format as a code formatter, but this only works for C-family languages. For java stuff, we can use astyle

### 3.14.5.2. Documentation

Software Packages		
	extra	doxygen

To generate a documentation from source code, I mostly use doxygen

### **3.14.5.3. Build tools**

Software	Packages
community	ninja

In addition to  ${\tt make},$  I'll often times use  ${\tt ninja}$  for my builds

### 3.14.6. Android file transfer

Software Packages		
extra	gvfs-mtp libmtp	

Now you should be able to see your phone inside either your preferred filemanager, in my case thunar, or gigolo<sup>AUR</sup>.

If you want to access the android's file system from the command line, you will need to either install and use  $simple-mtpfs^{AUR}$ , or adb

### **3.14.6.1.** simple-mtpfs<sup>AUR</sup>

Software Packages		
AUR	simple-mtpfs	

#### Edit /etc/fuse.conf to uncomment

/etc/fuse.conf

```
user_allow_other
```

#### and mount the android device

```
dustvoice@DustArch ~

$ simple-mtpfs -l
dustvoice@DustArch ~

$ mkdir ~/mnt
dustvoice@DustArch ~

$ simple-mtpfs --device <number> ~/mnt -allow_other
```

### and respectively unmount it

```
dustvoice@DustArch ~

$ fusermount -u mnt
dustvoice@DustArch ~

$ rmdir mnt
```

Software Packages		
community	android-tools	

Kill the adb server, if it is running

```
dustvoice@DustArch ~
$ adb kill-server
```

If the server is currently not running, adb will output an error with a Connection refused message.

Now connect your phone, unlock it and start the adb server

```
dustvoice@DustArch ~
$ adb start-server
```

If the PC is unknown to the android device, it will display a confirmation dialog. Accept it and ensure that the device was recognized

```
dustvoice@DustArch ~
$ adb devices
```

Now you can push/pull files.

```
dustvoice@DustArch ~
$ adb pull /storage/emulated/0/DCIM/Camera/IMG.jpg .
dustvoice@DustArch ~
$ adb push IMG.jpg /storage/emulated/0/DCIM/Camera/IMG2.jpg
dustvoice@DustArch ~
$ adb kill-server
```

Of course you would need to have the *developer options* unlocked, as well as the *USB debugging* option enabled within them, for adb to even work.

## 3.14.7. Partition management

Software Packages		
extra gparted parted		

You may also choose to use a graphical partitioning software instead of fdisk or cfdisk. For that you can use gparted. Of course there is also the console equivalent `parted.

### **3.14.8. PDF viewer**

Software Packages		
extra evince		
community	mupdf	

To use <code>asciidoctor-pdf</code>, you might be wondering how you are supposed to open the generated PDFs using the GUI.

If you want to have changes made to the PDF reflected immediately in the viewer, you would need evince instead of mupdf, but mupdf has a more minimalistic interface, which comes in handy when using a tiling window manager.

### 3.14.9. Process management

Software Packages			
extra	htop xfce4-taskmanager		

The native tool is top.

The next evolutionary step would be <a href="https://h

If you prefer a GUI for that kind of task, use xfce4-taskmanager.

### 2.3.

Just some additional software related to videos.			
,			

### 3.14.10.1. Live streaming a terminal session

Software Packages	
community	tmate

For this task, you'll need a program called tmate.

## 3.15. Additional GUI software

As you now have a working graphical desktop software to utilize your newly gained power.	environment,	you	might	want	to	install	some

#### 3.15.1. Session Lock

Software Packages	
community	i3lock xss-lock

Probably the first thing you'll want to set up is a session locker, which locks your X-session after resuming from sleep, hibernation, etc. It then requires you to input your password again, so no unauthorized user can access you machine.

I'll use xss-lock to hook into the necessary systemd events and i3lock as my locker.

I have placed the required command to start xss-lock with the right parameters inside my i3 configuration file.

If you use something other than i3, you need to make sure this command gets executed upon start of the X-session

xss-lock -- i3lock -n -e -c 333333

### 3.15.2. xfce-polkit<sup>AUR</sup>

Software Packages		
AUR	xfce-polkit	

In order for GUI applications to acquire sudo permissions, we need to install a PolicyKit authentication agent.

We could use <code>gnome-polkit</code> for that purpose, which resides inside the official repositories, but I decided on using <code>xfce-polkit</code><sup>AUR</sup>.

Now you just need to startup xfce-polkit<sup>AUR</sup> before trying to execute something like gparted and you'll be prompted for your password.

As I already launch it as a part of my i3 configuration, I won't have to worry about that.

## 3.15.3. Desktop background

Software Packages		
extra	nitrogen	

You might want to consider installing nitrogen, in order to be able to set a background image

### 3.15.4. Compositing software

Software Packages		
community	picom	

To get buttery smooth animation as well as e.g. smooth video playback in brave without screen tearing, you might want to consider using a compositor, in my case one named picom

In order for obs' screen capture to work correctly, you need to kill picom completely before using obs.

```
dustvoice@DustArch ~
$ killall picom
```

or

```
dustvoice@DustArch ~

$ ps aux | grep picom
dustvoice@DustArch ~

$ kill -9 <pid>
```

### 3.15.5. networkmanager applet

Software Packages		
extra	network-manager-applet	

To install the NetworkManager applet, which lives in your tray and provides you with a quick method to connect to different networks, you have to install the network-manager-applet package

Now you can start the applet with

```
dustvoice@DustArch ~
$ nm-applet &
```

If you want to edit the network connections with a more full screen approach, you can also launch nm-connection-editor.

The nm-connection-editor doesn't search for available Wi-Fis. You would have to set up a Wi-Fi connection completely by hand, which could be desirable depending on how difficult to set up your Wi-Fi is.

## 3.15.6. Show keyboard layout

Software Packages	
AUR	xkblayout-state

To show, which keyboard layout and variant is currently in use, you can use xkblayout-stateAUR

Now simply issue the  ${\tt layout}$  alias, provided by my custom  ${\tt zsh}$  configuration.

	Soft	ware Packages		
o copy something from the	terminal to the	x <mark>org</mark> clipboard, u	se xclip	

## 3.15.8. Taking screen shots

Software Packages	
community	scrot

For this functionality, especially in combination with rofi, use scrot

scrot ~/Pictures/filename.png then saves the screen shot under ~/Pictures/filename.png.

## 3.15.9. Image viewer

Software Packages	
extra ristretto	

Now that we can create screen shots, we might also want to view those

dustvoice@DustArch ~
\$ ristretto filename.png

### 3.15.10. File manager

Software Packages		
extra	gvfs thunar	
AUR	gigolo	

You probably also want to use a file manager. In my case, thunar, the xfce file manager, worked best.

To also be able to mount removable drives, without being root or using sudo, and in order to have a GUI for mounting stuff, you would need to use gigolo<sup>AUR</sup> and gvfs.

## 3.15.11. Archive manager

Software Packages		
extra	cpio unrar unzip zip	
community	xarchiver	

As we now have a file manager, it might be annoying, to open up a terminal every time you simply want to extract an archive of some sort. That's why we'll use xarchiver.

#### **3.15.12. Web browser**

Software Packages		
AUR	brave-bin	
community	browserpass	

As you're already using a GUI, you also might be interested in a web browser. In my case, I'll install brave-bin<sup>AUR</sup>, as well as browserpass from the official repositories, in order to use my passwords in brave.

We still have to setup browserpass

```
dustvoice@DustArch ~

$ cd /usr/lib/browserpass
dustvoice@DustArch /usr/lib/browserpass
$ make hosts-brave-user
dustvoice@DustArch /usr/lib/browserpass
$ make policies-brave-user
dustvoice@DustArch /usr/lib/browserpass
$ cd ~
```

Now the only thing left is, to fire up brave and install the browserpass extension from the chrome store.

### 3.15.12.1. Entering the dark side

Software Packages	
AUR tor-browser	

You might want to be completely anonymous whilst browsing the web at some point. Although this shouldn't be your only precaution, using tor-browser<sup>AUR</sup> would be the first thing to do

You might have to check out how to import the gpg keys on the AUR page of torbrowser.

# 3.15.13. Office utilities

Software Packages	
extra	libreoffice-fresh

I'll use libreoffice-fresh for anything that I'm not able to do with neovim.

#### 3.15.13.1. Printing

```
Software Packages

avahi cups cups-pdf nss-mdns print-manager
system-config-printer
```

In order to be able to print from the gtk print dialog, we'll also need system-config-printer and print-manager.

```
dustvoice@DustArch ~

$ sudo systemctl enable avahi-daemon.service
dustvoice@DustArch ~

$ sudo systemctl start avahi-daemon.service
```

Now you have to edit /etc/nsswitch.conf

so this line

/etc/nsswitch.conf

```
hosts: files mymachines myhostname resolve [!UNAVAIL=return] dns
```

becomes this line

/etc/nsswitch.conf

```
hosts: files mymachines myhostname mdns4_minimal [NOTFOUND=return] resolve [!UNAVAIL=return] dns
```

Now continue with this

```
dustvoice@DustArch ~

$ avahi-browse --all --ignore-local --resolve --terminate
dustvoice@DustArch ~

$ sudo systemctl enable org.cups.cupsd.service
dustvoice@DustArch ~

$ sudo systemctl start org.cups.cupsd.service
```

Just open up system-config-printer now and configure your printer.

To test if everything is working, you could open up brave, then go to **Print** and then try printing.

### .............

3.15.14. Communication		
Life is all about communicating. Here are some pieces of software to do exactly that.		

#### 3.15.14.1. Email

Software Packages	
extra	thunderbird

There is nothing better than some classical email.

# 3.15.14.2. Telegram

Software Packages	
community	telegram-desktop

You want to have your telegram messages on your desktop PC?

# 3.15.14.3. TeamSpeak 3

Software Packages		
community	teamspeak3	

Wanna chat with your gaming friends and they have a teamspeak3 server?

#### 3.15.14.4. Discord

Software Packages		
community	discord	

You'd rather use discord?

#### 3.15.15. Video software

Just some additional softwa	re related to videos		

## **3.15.15.1. Viewing video**

Software Packages		
extra	vlc	

You might consider using vlc

# 3.15.15.2. Creating video

Software Packages		
AUR	obs-studio-git	

obs-studio-git<sup>AUR</sup> should be the right choice

#### 3.15.15.2.1. Showing keystrokes

Software Packages		
AUR	screenkey	

In order to show the viewers what keystrokes you're pressing, you can use something like  $screenkey^{AUR}$ 

For ideal use with obs, my dotfiles repository already provides you with the screenkey-obs alias for you to run with zsh.

## 3.15.15.3. Editing video

Software Packages		
AUR	davinci-resolve	

In my case, I'm using davinci-resolve<sup>AUR</sup>.

## 3.15.15.4. Utilizing video

Software Packages	
AUR	teamviewer

Wanna remote control your own or another PC? teamviewer AUR might just be the right choice for you

#### 3.15.16. Audio Production

You might have to edit /etc/security/limits.conf, to increase the allowed locked memory amount.

In my case I have 32GB of RAM and I want the audio group to be allocate most of the RAM, which is why I added the following line to the file

/etc/security/limits.conf

```
@audio - memlock 29360128
```

#### 3.15.16.1. Ardour

Software Packages	
community	ardour

To e.g. edit and produce audio, you could use ardour, because it's easy to use, stable and cross platform.

```
Software Packages

extra ffmpeg
```

Ardour won't natively save in the mp3 format, due to licensing stuff. In order to create mp3 files, for sharing with other devices, because they have problems with wav files, for example, you can just use ffmpeg.

and after that we're going to convert in.wav to out.mp3

```
dustvoice@DustArch ~
$ ffmpeg -i in.wav -acodec mp3 out.mp3
```

#### 3.15.16.2. Reaper

Software Packages	
AUR	reaper-bin

Instead of ardour, I'm using reaper, which is available for linux as a beta version, in my case more stable than ardour and more easy to use for me.

#### 3.15.17. Virtualization

Software Packages	
community	virtualbox virtualbox-host-modules-arch

You might need to run another OS, for example Mac OS, from within Linux, e.g. for development/testing purposes. For that you can use virtualbox.

Now when you want to use virtualbox just load the kernel module

```
dustvoice@DustArch ~
$ sudo modprobe vboxdrv
```

and add the user which is supposed to run virtualbox to the vboxusers group

```
dustvoice@DustArch ~
$ sudo usermod -a G vboxusers $USER
```

and if you want to use rawdisk functionality, also to the disk group

```
dustvoice@DustArch ~
$ sudo usermod -a G disk $USER
```

Now just re-login and you're good to go.

# 3.15.18. Gaming

Software Packages		
extra	pulseaudio pulseaudio-alsa	
community	lutris	
multilib	lib32-libpulse lib32-nvidia-utils steam	

The first option for native/emulated gaming on Linux is obviously steam.

The second option would be lutris, a program, that configures a wine instance correctly, etc.

### 3.15.19. Wacom

Software Packages	
extra	libwacom xf86-input-wacom

In order to use a Wacom graphics tablet, you'll have to install some packages

You can now configure your tablet using the  ${\tt xsetwacom}$  command.

#### 3.15.20. VNC & RDP

Software Packages		
extra	libvncserver	
community	remmina	
AUR	freerdp	

In order to connect to a machine over VNC or to connect to a machine using the Remote Desktop Protocol, for example to connect to a Windows machine, I'll need to install freerdp<sup>AUR</sup>, as well as libvncserver, for RDP and VNC functionality respectively, as well as remmina, to have a GUI client for those two protocols.

Now you can set up all your connections inside remmina.

# 4. Upgrading the system

You're probably wondering why this gets a dedicated section.

You'll probably think that it would be just a matter of issuing

```
dustvoice@DustArch ~
$ sudo pacman -Syu
```

That's both true and false.

You have to make sure, **that your boot partition is mounted at /boot** in order for everything to upgrade correctly. That's because the moment you upgrade the linux package without having the correct partition mounted at /boot, your system won't boot. You also might have to do grub-mkconfig -o /boot/grub/grub.cfg after you install a different kernel image.

If your system **indeed doesn't boot** and **boots to a recovery console**, then double check that the issue really is the not perfectly executed kernel update by issuing

```
root@DustArch ~
$ uname -a
```

and

```
root@DustArch ~
$ pacman -Q linux
```

The version of these two packages should be exactly the same!

If it isn't there is an easy fix for it.

# 4.1. Fixing a faulty kernel upgrade

First off we need to restore the old linux package.

For that note the version number of

```
root@DustArch ~
$ uname -a
```

Now we'll make sure first that nothing is mounted at /boot, because the process will likely create some unwanted files. The process will also create a new /boot folder, which we're going to delete afterwards.

```
root@DustArch ~
$ umount /boot
```

Now cd into pacman's package cache

```
root@DustArch ~
$ cd /var/cache/pacman/pkg
```

There should be a file located named something like linux-<version>.pkg.tar.xz, where <version> would be somewhat equivalent to the previously noted version number

Now downgrade the linux package

```
root@DustArch ~
$ pacman -U linux-<version>.pkg.tar.xz
```

After that remove the possibly created /boot directory

```
root@DustArch ~

$ rm -rf /boot
root@DustArch ~

$ mkdir /boot
```

Now reboot and mount the boot partition, in my case an EFI System Partition.

Now simply rerun

```
dustvoice@DustArch ~
$ sudo pacman -Syu
```

and you should be fine now.

Consider setting up an fstab entry for the boot partition, in order to avoid such dilemma in the future.

See fstab for more.

# 5. Additional notes

If you've printed this guide, you might want to add some additional blank pages for notes.
